In sharp contrast with the slow, insidious, painless progress of chronic glaucoma, this form of the disease is very acute. Prodromal attacks of mistiness of vision, headaches, rainbow rings, and increasing presbyopia are common, and previous transitory subacute attacks may have occurred. The attack is characterised by pain radiating along the branches of the fifth nerve, or referred to the whole side of the head; there may be vomiting; the sight is rapidly reduced; the pupil is partly dilated, loses its circular shape, and fails to react to light stimulus; the cornea is œdematous, so that the fundus cannot be seen with the ophthalmoscope; and, above all, the tension of the eye is so increased that unless tenderness prevents a reasonable examination, no one, however inexperienced, will have difficulty in satisfying himself with regard to this crucial sign. Though the diagnosis of acute glaucoma need present little difficulty, the condition is still frequently overlooked, being labelled biliousness or gastritis with deplorable results. In such cases the eye itself, the cause of all the mischief, escapes treatment for several weeks, by which time the sight is most often completely and permanently destroyed. Acute glaucoma is a rather rare disease, but though a medical man may never have come across a case, he should always bear it in mind as a possibility. The chief local condition with which acute glaucoma may be confused is acute iritis; here again a mistaken diagnosis will lead to serious detriment to the eye, for the vigorous use of atropine, which is imperative in the treatment of iritis, is the worst possible treatment for glaucoma; differentiation between the two conditions, however, is seldom difficult, and we may conveniently tabulate the most helpful points in parallel columns:—

Acute Iritis.	*Acute Glaucoma.*
May occur at any age, but especially from 16 or 18 onwards.	Rare under the age of 45.
Pupil small and circular.	Pupil semi-dilated and irregular.
Sight somewhat dim.	Sight greatly deteriorated.
Tension normal or at most a little raised.	Tension greatly raised.
Corneal surface a little dulled.	Corneal surface very œdematous.
ATROPINE IMPERATIVE.	ATROPINE INADMISSIBLE.

Treatment.—The condition is so painful and the loss of sight so great, that patients seldom demur to operative treatment at the earliest possible moment; there is a great deal, however, that can be done to relieve the condition where arrangements for operation cannot immediately be carried out, and some surgeons advocate the employment of these preliminary measures as an adjunct in all cases; they consist of the instillation of eserine every quarter of an hour for six times; the application of two or three leeches to the temple of the same side; fomentations to the eye; and a smart purge; eserine should always be instilled into the other eye for fear of an attack of glaucoma in it. By these means the tension of the eye can usually be sensibly reduced, and the subsequent operation performed with a reduced risk.

Operation.—A general anæsthetic, preferably chloroform, is desirable, but if there is a serious contraindication to its use the operation may be carried out under local anæsthesia by injecting 2 per cent. novocaine solution under the conjunctiva and deeply into the orbit. There is a wide consensus of opinion amongst ophthalmic surgeons that a rather wide iridectomy is the best form of treatment; the results are usually good and permanent.

R. FOSTER MOORE, B.Ch. Camb.,
F.R.C.S. Eng.,
Assistant Ophthalmic Surgeon, St. Bartholomew's Hospital; Surgeon, Moorfields Eye Hospital.

LONDON DERMATOLOGICAL SOCIETY.—The annual oration will be delivered at 4.30 P.M. on June 11th, at St. John's Hospital, Leicester-square, London, W., by Prof. M. Oppenheim, of Vienna, on Affections of the Skin Caused by Occupation and Profession. The oration will be illustrated by lantern slides in colour. Prof. Oppenheim will be the guest of the society at dinner at 6.30 P.M., at the Criterion Restaurant, in a private room (entrance in Regent-street). The price of each ticket is 7*s.* 6*d.* Fellows who desire to attend or to bring guests are asked to notify the secretary, Dr. A. Knyvett Gordon, at 10, Bedford-square, London, W.C. 1, before the meeting.

THE GENERAL MEDICAL COUNCIL.

DURING the remainder of the May session of the General Medical Council, which was continued throughout last week, the business consisted of the election of members to certain committees, the reception and discussion on various reports, and the consideration of penal cases.

Report of Committees.

The report of the *Examination Committee* was presented in two parts: Part I. giving an analysis of the annual tables for 1923, and Part II. relating to other matters, among which is a statement showing that the percentage of rejections in midwifery in the qualifying examinations is always lower than in either of the other two subjects, medicine and surgery, except in the case of Cambridge University. It is pointed out that this may be due to the fact that there is no clinical examination in midwifery in many centres, and also to the fact that it is a subject covering a smaller field and therefore more easily absorbed by the student.

While the Council's inspectors had reported favourably on the standards set and maintained in medicine and surgery, the inspector of midwifery had commented unfavourably on the omission of any practical test in the examinations on this subject in many of the final examinations; but the most recent returns show that while 17 bodies now hold such an examination, six do not—namely, the Universities of Cambridge, London, Liverpool, and Aberdeen, the English Conjoint Board, and the Apothecaries' Society of London; the University of Aberdeen, however, is about to introduce such an examination. In the University of London the percentage of rejections has fallen since candidates were not required to pass in all three subjects simultaneously. The percentage of rejections is highest by those bodies who are examining bodies only, since candidates are unknown to the examiners, and class records cannot be taken into consideration. The system of visitation to various examining bodies by members of the Committee has produced valuable results and will be continued for the present.

In the discussion which followed Mr. Waring said that in the case of a body such as the Conjoint Board, it would be impossible to accept class certificates, as they would come from so many sources as to render it impossible to reduce their value to a common denominator. Sir Francis Champneys said that ten minutes was far too short a time in which to examine a candidate in midwifery; the half-hour given at Cambridge was, however, quite satisfactory. He also thought that vaginal examinations were most important, but that many bodies objected to their taking place during qualifying tests. The report was agreed to.

The *Pharmacopœia Committee*, after considering certain correspondence on the matter, decided to suggest to the Council that it was desirable for this country to be represented at the proposed conference in Brussels in 1925. As regards the proposed International Bureau, however, more mature consideration would be needed before any decisions were arrived at. The committee suggested to the Council that the Lord President should be informed that assistance would be given in choosing delegates to the Brussels Conference, on the understanding that they should only report to the Government, and not be given any powers to bind either the Government or the Council. The report was agreed to.

The *Finance Report* shows an income of £2785, £196 more than in 1922. A heavy loss is still incurred in the publication of the Register, but the committee do not see how it could be made more informative in the manner of a directory and so increase its sale, which to the public at present is only about 200 copies a year. They feel that this pecuniary loss must be borne in carrying out this important statutory function.

Canada.—A new arrangement has been arrived at with the provinces of Alberta, Manitoba, New Brunswick, Nova Scotia, Ontario, and Prince Edward Island in relation to the registration of medical qualifications obtained in Canada being registered in this country. The arrangements with Quebec have not yet been concluded.

Penal Cases.

The following penal cases were deliberated on by the Council :—

The Case of Charles Russell Corfield.—This practitioner, registered as of 205, High-street, C. on M., Manchester, L.M.S.S.A. Lond., 1919, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you committed adultery with Gladys Nellie Frankish, a married woman, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated March 12th, 1923, and made absolute on Sept. 19th, 1923, in the case of Frankish *v.* Frankish and Corfield, in which you were the co-respondent ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council found that the facts alleged had not been proved to their satisfaction, and the case was accordingly dismissed.

The Case of Bryan Buckley Sharp.—This practitioner, registered as of 20, Rupert-street, London, W. 1, M.R.C.S. Eng., 1918, L.R.C.P. Lond., 1918, M.B., B.S., 1921, U. Lond., had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you on Jan. 30th, 1924, on the application of Miss Ada Sher for a Foreign Office passport (supported by her declaration in the usual form as to address, age, national status, and purpose for which required), made a declaration stating 'that to the best of my personal knowledge and belief of the above-made declaration of the said Miss Ada Sher is true, and that I can *from my personal knowledge* of her vouch her as a fit and proper person to receive a passport,' whereas you had no previous knowledge of the said Ada Sher, which declaration was untrue, misleading, and improper ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council found that laxity had been proved, but did not direct erasure from the Register.

The Case of Trevor Owen Williams. (Adjourned from Nov. 28th, 1922, and further adjourned from Nov. 30th, 1923.)—This practitioner, registered as of 4, Ullet-road, Liverpool, M.B., Ch.B., 1913, U. L'pool, M.R.C.S. Eng., 1913, L.R.C.P. Lond., 1913, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, and a captain in the Royal Army Medical Corps, you were on Oct. 14th, 1917, tried by a General Court Martial overseas on a charge of drunkenness whilst on active service in the field on Oct. 7th, 1917, of which charge you were found guilty and sentenced to be dismissed from His Majesty's Service, the finding and sentence being duly confirmed ; and that, being a registered medical practitioner, and while giving evidence before Mr. Justice Greer at the Assizes at Liverpool on Feb. 2nd, 1922, you were drunk, being reprimanded by the judge for being in that condition ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect ; and that you were at the city of Liverpool police-court convicted of the following misdemeanour, viz. : On June 23rd, 1922, of being drunk and disorderly and fined 10*s.* and 10*s.* doctor's fee."

At the conclusion of the hearing on Nov. 30th, 1923, the President announced the Council's decision as follows : "The Council, in consideration of the communications from the Salvation Army, have adjourned the further hearing of the case of Trevor Owen Williams until the May session of the Council in 1924."

At the resumed hearing of the case this session, the Registrar having read the notice of inquiry, the Council's solicitor placed the present facts of the case before the Council. He read correspondence which had taken place with the Salvation Army authorities, showing that Mr. Williams had not kept his promise to refrain from drink.

The Council, having deliberated on the matter, the President delivered the following judgment : "Mr. Williams : I have to inform you that you have been proved to have been convicted of the misdemeanours alleged against you in the notice of inquiry, and that the Registrar has been directed to erase your name from the Medical Register."

The Case of John Christie Forbes. (Adjourned from Nov. 28th, 1923.)—This practitioner, registered as of 40, Mayfield-road, Edinburgh, L.R.C.P. Edin., 1895, L.R.C.S. Edin., 1895, L.F.P.S. Glasg., 1895, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner : (1) You on numerous occasions permitted your clerk, Mrs. Wyman, to sign in your name and issue certificates required for National Health Insurance purposes, and that in many of such cases you had not examined the patient although so stated in the certificates, which were untrue, misleading, or improper. The insured persons and the certificates in question were as follows—viz. : (*a*) Robert Martin, 20 certificates ; (*b*) William Stewart, 19 ; (*c*) Archibald Harris, 14 ; (*d*) N. Strachan, 18. (2) You permitted the said Mrs. Wyman on three occasions to sign in your name and issue orders for three separate prescriptions for an insured person, Archibald Sharp, without having first seen or examined him ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council did not see fit to erase Dr. Forbes's name from the Register.

The Case of Nowroji Merwanji Tarachand.—This practitioner, registered as of Mansfield, Nottingham, M.R.C.S. Eng., 1893, L.R.C.P. Lond., 1893, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you : (1) On August 4th, 1923, signed in anticipation of your holiday a number of intermediate certificates of incapacity for work for eight insured persons on your list, which certificates stated that you had examined these person on certain dates—namely, August 6th, 7th, and 8th, 1923—whereas on such dates you were away on your holiday ; (2) on your return from such holiday signed a first certificate and notice of sickness for an insured person on your list which you antedated, and which stated that you had examined the patient on August 8th (such certificates being required for National Health Insurance purposes) ; which certificates were untrue, misleading, or improper ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

In this case judgment was postponed till May, 1925.

The Case of Shridhar Bheekajee Gadgil.—This practitioner, registered as of Mhow, India, L.M.S.U. Bombay, 1898, M. 1900, F. 1915, R.C.S. Eng., L.R.C.P. Lond., 1900, had been summoned to appear before the Council on the following charge :—

"That you were on Sept. 21st, 1923, at the Marlborough-street police-court, convicted of the following misdemeanour—namely, of insulting behaviour, and were fined 40*s.* and 2 guineas costs, or 11 days' imprisonment ; and that on your appeal on Oct. 12th, 1923, to the County of London Quarter Sessions from the decision of the said court the said decision was confirmed, and you were ordered to pay the taxed costs of the respondent of the said appeal."

Judgment was postponed till the May session, 1925.

The Case of Henry Love.—This practitioner, registered as of Avoca, Mitcham, Surrey, M.B., U. Dub., 1878, L.R.C.S. Irel., 1878, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you by your countenance or assistance knowingly enabled Mrs. Elizabeth Woolsey and Mrs. Munt, women not certified under the Midwives Acts, 1902 and 1918, to attend women in childbirth, and Mrs. Marie Stiler a woman not entitled to practise midwifery in the administrative county of Surrey, also to attend women in childbirth, under cover or pretence that such women were attended or to be attended by you or by the said Mrs. Woolsey, Mrs. Munt, or Mrs. Stiler, under your direction, and that in some of these cases you signed maternity benefit certificates and gave notifications of birth, thereby enabling each of them, the said Mrs. Woolsey, Mrs. Munt, and Mrs. Stiler, in contravention of the said Acts, to practise as a midwife ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

Judgment was postponed till May, 1925.

The Case of James Robert Stott, O.B.E. (Consideration adjourned from May 31st, 1923.)—This practitioner, registered as of 202, Ewell-road, Surbiton, Surrey, M.B., Ch.B., 1910, B.Sc. (P.H.), 1912, M.D., 1918, U. Edin., had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you by your countenance or assistance knowingly enabled one Annie Hennings, a woman not certified under the Midwives Act, 1902, to attend women in childbirth under cover or pretence that such women were attended or to be attended by you or by her under your direction, and that in some of such cases you signed maternity benefit certificates, thereby enabling the said Annie Hennings in contravention of the said Act to practise as if she were certified thereunder ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

After a short deliberation, the President delivered judgment in this case as follows : "Mr. Stott : I have to inform you that the Council have considered the evidence as to your conduct during the interval which you have tendered, and they have resolved : That they do not see fit to direct the Registrar to erase your name from the Medical Register."

The Case of Henry Bowen Perkins.—This practitioner, registered as of 105, Dock-road, Tilbury, Essex, M.R.C.S. Eng., 1890, L.R.C.P. Lond., 1890, had been summoned to appear before the Council on the following charge :—

"That you were on Nov. 13th, 1914, at the Grays Petty Sessions convicted of being drunk, and were fined 1*s.* and 4*s.* costs ; that you have abused your position as a medical man by behaving improperly at your surgery to the following persons—viz. : (1) On or about Nov. 21, 1922, to Mrs. ——, who had called for a certificate for her husband, who was a patient of yours ; (2) on or about Jan. 28th, 1924, to Mrs. ——, who was a patient of yours ; and (3) on or about Feb. 19th, 1924, to Miss ——, who was a patient of yours ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

After deliberation, the President announced the judgment of the Council as follows : "Mr. Perkins : I have to inform you that the conviction alleged against you in November, 1914, of a misdemeanour has been proved to the satisfaction of the Council. The facts alleged against you in regard to the abuse of your position as a professional man, however, have not been proved, and the case is dismissed."

The Case of Jonathan Allan Thornhill.—This practitioner, registered as of Ingleside, Newnham, Glos., L., L.M., 1891, R.C.P. Irel., L., L.M., 1891, R.C.S.Irel., had been summoned to appear before the Council on the following charge :—

"That being a registered medical practitioner : (1) On April 15th and 18th, 1923, while attending a Mr. J. P., who was seriously ill from influenza, you were so far under the influence of drink that your power of judgment and sense of responsibility were affected to a degree rendering you unfit to be in charge of a serious case of illness. (2) On April 23rd, 1923, you gave to the said J. P., a National Health Insurance certificate stating that you had examined him on that date and that he was incapable of work by reason of broncho-pneumonia, whereas you had not seen or examined the said J. P. on that date or since April 18th, 1923 ; which certificate was untrue, misleading, or improper ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council found that the first part of the charge had not been proved to their satisfaction, and as regards the second part they suspended judgment till November of this year.

The Case of Henry Spencer Hughes.—This practitioner, registered as of Galen House, Lozells-road, Birmingham, M.R.C.S. Eng., 1894, L.R.C.P. Lond., 1894, had been summoned to appear before the Council on the following charge :—

"That, being a registered medical practitioner, you by your countenance or assistance knowingly enabled one A. D., a woman not certified under the Midwives Acts, 1902 and 1918, to attend women in childbirth under cover or pretence that such women were attended or to be attended by you or by her under your direction, and that in some of such cases you signed maternity benefit certificates and gave notifications of birth, thereby enabling the said A. D., in contravention of the said Acts, to practise as if she were certified thereunder ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The facts having been proved to the satisfaction of the Council, judgment was postponed till the May session, 1925.

The Case of Harold Walmsley.—This dental practitioner was registered on Dec. 29th, 1919, as of Northwood, Prestwich Park South, Manchester, L.D.S. V.U. Manc., 1919. The Dental Board, having considered the complaint against the said Harold Walmsley, reported as follows :—

"The said Harold Walmsley did not attend and was not represented. Service of the notice of inquiry was proved by the solicitor. The following facts were established by the evidence : Harold Walmsley was convicted at the assizes held at Northampton on Jan. 21st, 1924, of indecently assaulting a male person and of committing an act of gross indecency with a male person and sentenced to nine months' imprisonment in the second division. The evidence before the board consisted of a certified copy of the said conviction, a report of the trial from the *Northampton Mercury* of Jan. 25th, 1924, and three testimonials dated in April and May, 1924. The board have, therefore, resolved to transmit to the General Medical Council their finding—namely, that the name of Harold Walmsley ought to be erased from the Register."

Mr. Walmsley did not appear, nor was he represented. The President announced the decision of the Council as follows : "I have to announce that Harold Walmsley, having been found by the Dental Board to have been convicted of the misdemeanour alleged against him in the notice of inquiry, the Council has directed the Registrar of the Dental Board to erase from the Dentists Register the name of Harold Walmsley."

The Case of Abraham Frank (or Franks).—He was registered on Sept. 4th, 1922, as of 201, High-street, Shoreditch, London, E. 1, Dentist, 1921. The Dental Board, having considered the complaint against the said Abraham Frank, reported as follows :—

"The said Abraham Frank did not attend and was not represented. Service of the notice of inquiry was proved by the solicitor. The following facts were established by the evidence : On the prosecution of the Dental Board, the said Abraham Frank was convicted on March 25th, 1924, at the Old-street police-court, London, of aiding and abetting his son, Percy Frank (or Franks) to practise dentistry, he not being registered in the Dentists Register, and was fined 20 guineas and 5 guineas costs. On the same day the said Percy Frank was also convicted of practising dentistry, not being registered so to do, and was fined 20 guineas and 5 guineas costs. Abraham Frank is, or was, a hairdresser, and it did not appear that he had ever practised dentistry or was capable of doing so. His son, the said Percy Frank, who was under the age required by the provisions of the Dentists Act, 1921, for registration, practised dentistry at 201, High-street, Shoreditch, in the name of his father. Abraham Frank was on the premises at 201, High-street, Shoreditch, in attendance in the rooms where his son was practising, and had covered him in such practice. Abraham Frank had applied for registration under Section 3 (1) (*a*) of the Dentists Act, 1921, and had lodged the statutory declaration required by the regulations of the Dental Board. It appeared from the evidence given at the police-court that the statutory declaration had, in fact, been signed by the said Percy Frank in the name of his father, and that the father could sign his own name but not well, nor could he read writing very well. The evidence before the Board consisted of the accompanying documents : (1) A certified copy of the said conviction ; (2) the depositions taken at the Old-street police-court on March 25th, 1924, and the documents exhibited thereto. The Board, therefore, resolved to transmit to the General Medical Council their finding—namely, that the name of Abraham Frank ought to be erased from the Register."

Mr. Frank did not appear in answer to his notice nor was he represented. The Dental Board were represented by their solicitor, who stated that he had nothing to add to the report and finding. The President announced the decision of the Council as follows : "I have to announce that the Dental Board having found the facts alleged against Abraham Frank in the notice of inquiry to have been proved, the Council have directed the Registrar of the Dental Board to erase the name of Abraham Frank from the Dentists Register."

The President announced that the Registrar of the Dental Board had been directed to restore to the Dentists Register the name of Walter Ernest Tate.

Medicine and the Law.

Russell v. Russell in the House of Lords.

Judgment was delivered on May 30th in the House of Lords in the Russell divorce suit which for many months has excited the attention of the public and which, owing to the nature of the principal issue involved and of the evidence relating to it, may fairly be said to possess special interest for medical men. The decision arrived at does not, or may not, absolutely conclude the question of divorce raised by the petition, but only disposes of the main issue raised in the Court of Appeal, and since then in the House of Lords, as to whether evidence given by Mr. Russell in the divorce court regarding the marital relations between himself and his wife was properly admitted. In Lord Birkenhead's words this question was whether by the law of England evidence of non-access may in proceedings for divorce be tendered by a spouse and received by a court with the object, or possible result, of bastardising a child of the marriage. The House of Lords, by a majority consisting of Lord Birkenhead, Lord Finlay, and Lord Dunedin, has answered this question in the negative, Lord Sumner and Lord Carson dissenting. Consequently, if the petitioner proceeds further in the particular case under decision, his own evidence must be excluded, and he must rely on such other evidence as he may be able to tender.

Lord Birkenhead, in his judgment,[1] after stating the issue involved, referred at length to the pronouncement of the law enunciated by Lord Mansfield in the case of Goodright *v.* Moss in 1777: "The law of England is clear that the declarations of a father or mother cannot be admitted to bastardise the issue born after marriage." This, his lordship held, covered the case of evidence introduced for the purpose of obtaining divorce, and had not been modified or altered by the Act of 1869, Section 3 of which enables husbands and wives to give evidence in proceedings instituted in consequence of adultery. Lord Birkenhead laid stress on the anomaly which would arise if evidence should be admitted in divorce proceedings, which would tend to prove a child born in wedlock to be illegitimate, whereas it could not be admitted, when at some other date and in other proceedings, the declaration of the child's illegitimacy might be sought. According to his lordship, Lord Mansfield's declaration that the rule was founded upon "decency, morality, and public policy," did not have the meaning ascribed to it by the Court of Appeal, and that court had gone "strangely wrong" upon this point. What Lord Mansfield meant was that a deeply-seated domestic and social policy rendered it unbecoming that evidence should be received from such a source and with such a possible result; it had nothing to do with the reception in divorce courts of evidence of an "indecent" character. In his lordship's view a long series of later judgments had affirmed and re-stated the rule in Goodright's case. The Act of 1869 did not make husbands and wives competent witnesses upon all points relevant to the issue between them, but only enabled them to give evidence not otherwise inadmissible. The witnesses had become competent but they might not give this evidence.

Lord Finlay and Lord Dunedin delivered concurring judgments.

Lord Sumner, in a very learned and exhaustive judgment,[1] dissented from the view of Lord Birkenhead, holding that, although the rule laid down by Lord Mansfield applies still in cases the object of which is to establish the illegitimacy or legitimacy of a child born during wedlock, it should not be applied in cases in which the object aimed at is the dissolution of marriage, and in which the husband and wife are the only witnesses having actual knowledge of the facts as to which they can give evidence. Lord Sumner agreed that Lord Mansfield did not exclusively refer to what is in itself unseemly or disgusting, but he protested against the injustice done to the memory of the late Lord Sterndale, in thinking that he had in the Court of Appeal gone "strangely wrong" in his application of Lord Mansfield's word "decency." Lord Sumner was "afraid that the sanctity of marriage intercourse passed into the limbo of lost causes and impossible loyalties in 1857."[2] "The divorce court sits," Lord Sumner continued, "that the secrets of married life may be divulged." There could be nothing but prejudice to decorum if it were made plain that material facts were being kept from the court. It appeared to him a logical and a legal solution to recognise that a divorce petition and a legitimacy issue are distinct, and to apply Lord Mansfield's rule to legitimacy issues only. It had been said that absurd and incongruous results might follow. It might be found in one case that a bastard child had been born and a marriage might so be dissolved, and yet the same child might have to be declared to be no bastard in legitimacy proceedings; but this need not cause dismay. The same results would have followed if in the trial of the divorce case non-access had been proved by evidence other than that of the husband. Other incongruities could be discovered in other instances of two trials occurring in the courts and relating to the same facts. Lord Mansfield's rule had never been applied in divorce cases, and in Lord Sumner's view it was undesirable to extend its scope. He therefore dissented from the views of Lord Birkenhead, Lord Finlay, and Lord Dunedin, and held that the evidence was rightly admitted and that the appeal should be dismissed. Lord Carson followed with a judgment to the same effect.

Nystagmus and Suicide.

A case of some importance was decided at Leigh, Lancashire, by Judge Mellor on May 30th. The widow of a miner, aged 46 years, claimed compensation from the colliery proprietors for the loss of her husband, who had worked at one of their collieries for 30 years. Deceased had been certified as suffering from nystagmus last year, and before that time was described as "a bright, cheerful man." He tried work on the surface, but had to give it up. Later he committed suicide. For the applicant, Dr. C. H. Melland, consulting physician to the Royal Infirmary, Manchester, testified that miner's nystagmus led to depression and a morbid fear of going blind, often accompanied by dismal forebodings, nightmare, and fearful dreams. A man in that state was always liable to take his life. The judge said he had had a somewhat similar case two years ago at Leigh, when he awarded compensation and his decision, which was the first of its kind, was later upheld in the Court of Appeal. He considered that deceased deliberately committed suicide and that the suicide was directly due to nystagmus. He awarded the widow £297 with costs.

Coroners and Fires.

Dr. F. J. Waldo, coroner for the City of London and Borough of Southwark, in his annual report for 1923, records that in that year he held 173 inquiries into fires under the City of London Fire Inquests Act, as against 189 in 1922 and 236 in 1921, the average number of such fires in the last 22 years being 152. Dr. Waldo is a strong believer in the usefulness of the powers which he thus exercises, and recommends the holding of inquests after fires, whether there has been loss of life or not, throughout the country, instead of as now exclusively in the City. The subject has been considered, he points out, by the Royal Commission on Fire Brigades and Fire Prevention, which published its report in 1923, and recommended that inquiries into the cause of fires should be held in all appropriate cases. The Commission advised that the holding of such investigations in suspicious cases would act as a deterrent against arson, as well as being likely to elicit valuable information on technical questions. A majority of the Commission, however, also recommended that the investigation of fires should be held not by coroners, but by persons with technical qualifications, apparently with the idea that these should be experts in construction, in building materials, and in other technical matters likely to be included for consideration in the scope of such inquiries. Dr. Waldo, very reasonably, supports the view of the chairman of the Royal Commission, in holding that the coroner, as an independent judicial officer, in many instances qualified as a lawyer, and having the experience and machinery of his office at his command, should be fully competent and better equipped than anyone else for the task. His undertaking it would also prevent the duplication of the inquiry which otherwise would take place, whenever death through a fire might render an inquest of the usual kind necessary. He suggests that the matter should be considered when the law relating to coroners is revised. Its revision, it need hardly be pointed out, has been urged, promised, and postponed so long that those interested have almost abandoned the expectation of it taking place. The Act now in force was passed in 1887.

Special Articles.

ENCEPHALITIS LETHARGICA:

SUGGESTED ACTION BY MEDICAL OFFICERS OF HEALTH.

ENCEPHALITIS lethargica was made compulsorily notifiable throughout England and Wales from Jan. 1st, 1919. In present knowledge the action which medical officers of health are able to take on receipt of notifications or on learning of suspected cases is necessarily limited, and is set forth in the concluding section of the Memorandum on Encephalitis Lethargica just issued by the Ministry of Health, which is the subject of a leading article in the present issue of THE LANCET. The Memorandum regards it as very important that action should proceed on the following lines :—

(*a*) Full determination of the associated conditions and any facts which may throw light on the epidemiology of the disease.

(*b*) Search for mild and abortive cases.

(*c*) Aiding in any practicable pathological investigation and in obtaining material for the purpose.

(*d*) Aiding in securing the treatment of the case in hospital or otherwise.

(*e*) Enjoining the precautions required in the case of a disease apparently capable of transmission from person to person, especially through mild or abortive cases capable of carrying infection ; and

(*f*) "Following up" and recording the after-history of patients ; in particular, as to any mental after-effects which may be observed. In this connexion inquiry should also be made into the previous history of children who began to exhibit changes in behaviour or unusual accentuation of undesirable qualities ; these symptoms not infrequently point to an overlooked attack of epidemic encephalitis at an earlier date.

Specimens of cerebro-spinal fluid from cases or suspected cases of encephalitis lethargica can be sent, if desired, to the Ministry, for examination. The fluid should be withdrawn under strictly aseptic conditions, placed in a thoroughly sterilised bottle, free from disinfectants, and forwarded in accordance with the regulations of the Post Office to the Medical Officer (Med. 1), Ministry of Health, with particulars or reference to reports already sent. Medical officers of health are invited to take any action which they consider useful and practicable to secure post-mortem and pathological examinations by skilled workers who are investigating the disease.

Hospital and Nursing Facilities.—In view of the severity of the disease and the importance of good nursing, it is important to secure hospital treatment as far as possible. The isolation hospitals of local authorities should be available for this purpose. Any public nursing arrangements possessed by or arranged with the authority should be made available for cases treated at home.

Precautions against Infection.—The other occupants of a house in which a case of encephalitis has occurred, or is being treated, may be assured that the disease is one of low infectivity, and that very slight risk is run by association with the patient. At the same time it is desirable that such association should be limited to what is necessary for proper care and nursing, and the patient should be well isolated in a separate room.

School-children in the affected household may be kept from school, as a precautionary measure, for three weeks after the isolation of the patient. There is no necessity to place restriction on the movements of other occupants provided they are frequently examined and remain well. Those in contact with the case, however, may be advised to use antiseptic nasal sprays or douches and to gargle the throat with solutions such as those advised for influenza. For example, any of the following :—

(1) One per cent. solution of peroxide of hydrogen.

(2) A solution of permanganate of potash, 1 in 5000, in 0·8 per cent. solution of chloride of sodium (common salt).

(3) Liquor sodæ chlorinatæ, 0·5 per cent.

These solutions can be used as ordinary throat gargles or snuffed up the nostrils, or applied by an efficient spray. Any persons in the infected household who suffer from sore-throat or other symptoms suggesting an abortive attack should be treated from this point of view and isolated as far as possible until they have recovered. The sick-room s thoroughly cleansed and disinfected at the end of the illness.

REPORT OF THE HEALTH OF THE ROYAL AIR FORCE, 1922.*

TAKING the Force as a whole, and excluding cases of less than 48 hours' duration, sickness incidence shows an increase of 16·7 per 1000 of strength on the figures for 1921. This increase can be almost entirely attributed to the increase in the number of cases of sandfly fever which occurred overseas. This disease accounted for over one-quarter of the total cases of sickness reported from abroad, and gave a case-rate per 1000 of strength of 230·6, as compared with 122·9 in 1921. The 48-hour cases have but little effect on the total non-effective rate caused by sickness, but it is interesting to note that whereas in the United Kingdom the number of such cases practically equals those of longer duration, abroad these minor cases outnumber those of greater severity in the approximate ratio of 10 to 7. In the following remarks cases of 48 hours' duration are not taken into account.

Sickness and Death-rates.

The average duration of each case was reduced by over two days from 19·6 in 1921 to 17·4 in 1922 ; a corresponding proportionate decrease in the number of days' sickness per head did not, however, result, owing to the increased case-incidence rate to which reference has already been made. There was, however, a reduction of nearly one day's sickness per head. The average number sick daily was reduced by 2·1 per 1000 to 24·6. The numbers finally invalided from the service decreased from 34·3 to 15·1 per 1000 of strength. This latter figure may presumably be taken as representing a more normal figure than those in previous years, during which the effects of the war were still being reflected in the invaliding figures. It is satisfactory to note that a smaller proportion of the strength overseas was invalided home during 1922. The death-rate per 1000 for the total force fell from 4·7 to 4·3. In the United Kingdom the case-rate shows a slight decrease of approximately 2 per 1000, the Mediterranean Littoral an increase of 54 per 1000, Iraq of 190 per 1000, and India a decrease of 532·9 per 1000. As a result of this marked reduction, the sickness-rate in India was the lowest for overseas areas, whereas in 1921 it was the highest. The decrease in sickness in India is attributed to improved sanitary and hygienic conditions and to the increased experience of tropical conditions of both officers and airmen. The chief diseases peculiar to tropical climates—namely, sandfly fever, dysentery, and malaria—are dealt with in detail in the chapter relating to overseas areas. In addition, the work of the R.A.F. Sandfly Fever Commission at Malta is described in a separate chapter. This chapter describes in detail the bionomics and life-history of the *Phlebotomus papatasii*, and gives the findings of the Commission. A summary of the experiments carried out at Malta is given, and also of the various recommendations as regards fly destruction, prevention of biting, and scale of fans for living quarters. The incidence of sandfly fever was to some extent counter-balanced by a decrease in the malaria case-rate, which dropped from 122·9 in 1921 to 73·6 in 1922.

---

* To be purchased directly from H.M. Stationery Office at the following addresses : Imperial House, Kingsway, London, W.C. 2 ; 28, Abingdon-street, London, S.W. 1 ; York-street, Manchester ; 1, St. Andrew's-crescent, Cardiff ; or 120, George-street, Edinburgh ; or through any bookseller. 1924. 3s.

Venereal Disease.—An investigation into the value of "914" in the treatment of chronic and relapsing cases of malaria was carried out in India. The results obtained were encouraging, although no definite conclusions were reached. The primary venereal disease-rate—already low—shows a further reduction of 3·2 per 1000, dropping from 22·4 to 19·2. These figures show a satisfactory state of affairs. A further attempt has been made to estimate the value of prophylaxis, and a table is given which summarises the data collected during 1921 and 1922.

Accidents and Injuries.

Causes of injury are again dealt with in detail under 11 main headings. Flying accidents accounted for 52 cases of injury and a further 50 deaths. These numbers are higher than in previous years, but it must be borne in mind that the amount of flying carried out has greatly increased. Taking this into account, it appears that the increase in the case-rate was considerably less than the proportionate increase in the amount of flying carried out during the year. It may also be observed that the increase of 14 in the number of deaths and the consequent increase in the death-rate is to a large extent accounted for by the fact that there were eight deaths as the result of three collisions in the air. During 1921 only one death was due to an accident of this nature. Accidents occurring whilst swinging propellers fell from 28 in 1921 to 21 in 1922. Accidents caused by a back-fire whilst starting motor engines were 48 in number, compared with 71 in 1921 and 102 in 1920. The number of cases of injury resulting from such accidents has been more than halved in three years, and this satisfactory feature is attributed to a more widespread knowledge of the correct method of starting engines. In addition, there were a further 122 cases of injury caused by motor accidents; of this number 81 were due to motor cycles. Accidents occurring during athletics again account for approximately one-third of the total number of cases of injury; sprained ankle (115) and traumatic synovitis of the knee-joint (100) are responsible for one-third of the total due to athletics. The nosological tables are presented in a condensed form, and a useful addition is the insertion of corresponding ratios for 1921 in respect of the main groups of diseases. (Statistics for the entire force are not available for comparison prior to 1921.)

Standards of Acceptance and Rejection.

The constitution of the Central Medical Board has remained unchanged, although its functions were enlarged during the year. All candidates for commissions in the service now undergo a physical examination by this Board. Interesting tables are given showing the average physical measurements of candidates accepted for flying duties. The chief causes for rejection are also given. The principal points of interest appear to be: (1) The uniformity of the results obtained in the total number of examinations conducted during 1921 and 1922. (2.) The lengthening of the time of return to normal from the exercise pulse-rate. This may in part be due to the slight rise in the rate of the pulse after exercise, noticeable in 1922. (3.) The chief cause for rejection again being the defects of vision, either alone or in association with defective physical efficiency.

As in previous years all officers were medically examined towards the end of the calendar year, and tables are given showing the average responses of all tests capable of numerical expression. Interesting features in these tables are: (1) A rise of 1 per cent. in the number of officers found fit for full flying duties, the figure being 78 as compared with 77 per cent. in 1921. This rise is more marked in the general duties branch, the essential function of which is flying. The increase in this branch is 3 per cent. (2) The close approximation of the percentages fit for full flying at home and abroad.

Apart from this increased percentage of officers found fit for full flying duties, the average response to the various tests shows, on the whole, an improvement on the results obtained in previous years. This result is the more satisfactory when it is borne in mind that the results in previous years were themselves well above the accepted standards. It is also noteworthy that the results obtained by many and diverse medical officers at home and abroad during 1921 and 1922 should show: (1) Such close approximation in the two years, pointing to uniformity of technique. (2) Such slight variation from the existing standards which were evolved from successful pilots during the war.

Recruiting is dealt with in a separate section, and various tables show the average physical measurements of accepted recruits classified by age, previous occupation, and geographical areas of residence. A further table shows the chief causes for rejection at R.A.F. recruiting depôts during the year.

Hygiene and sanitation are dealt with in detail under the various geographical areas at home and abroad. It is satisfactory to note that further improvements in conditions were effected during the year under review. Vaccination and inoculation are treated in a separate section, and the results of all vaccinations carried out during the year are given in detail in tabular form.

The report under review has been prepared on similar lines to previous reports. Condensation of all tables has been still further effected, and the tables have been simplified wherever possible. It is satisfactory to note that the price has been further reduced from 5*s.* to 3*s.*

SCOTTISH REPORT ON PUERPERAL MORBIDITY AND MORTALITY.

THE report of the Scottish Departmental Committee on Puerperal Morbidity and Mortality was published last week.[1] The Committee, it may be remembered, consisted of Lord Salvesen (chairman), Mrs. Mary Barbour, Dr. R. C. Buist, Miss M. E. Cairns, Dr. T. F. Dewar, Miss A. M. Fraser, Dr. Matthew Hay, and Dr. B. P. Watson, the complete term of reference being "to inquire into the incidence of puerperal morbidity and mortality in Scotland, with special reference to the causes contributing thereto, and to suggest any remedial measures."

The Committee in 12 meetings took the evidence of 40 well-selected witnesses, while the statistical information was supplied from various authoritative sources.

---

[1] Edinburgh: H.M. Stationery Office. 1924. 1*s.*

Puerperal Mortality.

The Registrar-General for Scotland furnished the Committee with the statistics of puerperal mortality in Scotland arranged in groups of causes and also according to district, age-group and otherwise, and in the appendix the following table is given showing the deaths from puerperal causes in Scotland during the period from 1855–1922 in decennial means.

Deaths from Puerperal Causes in Scotland.

Years.	Total deaths from puerperal fever.	Metria or puerperal fever.	Other diseases and accidents of childbirth.	Death-rate per 1000 births.		
				Total.	Puerperal fever.	Other diseases of childbirth.
1855–1864	512	180	332	4·9	1·7	3·2
1865–1874	595	213	382	5·1	1·8	3·3
1875–1884	660	252	408	5·2	2·0	3·2
1885–1894	658	306	353	5·3	2·5	2·8
1895–1904	605	246	359	4·6	1·9	2·7
1905–1914	703	216	488	5·6	1·7	3·9
1915–1922	704	194	510	6·2	1·7	4·5

The possible sources of fallacy in this table are pointed out inasmuch as the certificates of the cause of death do not necessarily show the fact of pregnancy, while the statistician in classifying the deaths where the certificate shows more than one cause may include these cases either as puerperal deaths or deaths with other origin.

Comparison of Deaths in Different Areas.

The mean death-rates in the various local areas of Scotland, years 1911–22, show considerable variations, but while landward areas show a higher rate than burgh areas, statistical expectation has been generally accurate, and whatever may be the factors which underlie the occurrence of puerperal mortality in Scotland they are common to the varieties of social condition which characterises the population. Comparison of the mortality-rates in England and Scotland is not possible, because in England when associated conditions have been present the puerperal relation has been omitted.

Puerperal Fever.

In 1897 notification of infectious diseases in Scotland became obligatory and puerperal fever was included in the list of diseases compulsorily notifiable, and has thus been under the cognisance of the public health officers. On this important subject the Scottish Departmental Committee find as follows :—

> " *Sepsis.*—From several of the larger areas we have had submitted to us careful analyses of the experience of these officers with regard to the frequency of puerperal fever, its mortality and the conditions amidst which it takes origin. From this evidence it is clear that while cases of puerperal fever are found in which no obstetrical manipulation or even assistance has been rendered, such cases are very rare, and the frequency of the fever is in close relation to the presence of delay or difficulty in the labour. The incidence is greater in first labours, in labours where some form of laceration has occurred, and in labours which have been terminated by instrumental or manual delivery."
>
> " *Notification.*—Several witnesses have represented the view that the notification of puerperal fever is by no means complete, and that this is due to the idea that failure to prevent sepsis suggests faulty professional attendance, which makes a doctor regard unwillingly the recognition of cases as septic. We have also had evidence from Glasgow and elsewhere that the practice of notification is improving, and that as a result the apparent case mortality in the cases which come to the notice of the medical officer of health is diminishing. It is much to be desired that the notification should be as nearly as possible complete. Without this complete knowledge it is not possible to measure accurately the social importance of puerperal fever ; and in many areas the notification is now the first step to hospital treatment, which is effective in proportion to the shortness of the illness that has preceded its initiation."

Professional Attendance.

The second part of the report deals with the work of the medical practitioner and the midwife in respect of the needs of the mother, and with the very important subject of antenatal care. Inquiry into the relation of environment to puerperal morbidity and mortality showed, as similar inquiries have shown, that the effect of bad housing and overcrowding are not of much weight statistically in causing puerperal troubles, while underfeeding has no effective connexion with maternal mortality ; but the care needed on the part of the practitioner extends from early pregnancy till her restoration to the non-pregnant normal, and all the witnesses before the Committee have been unanimous in their evidence that the most important avenue to the prevention of maternal mortality and morbidity is through antenatal care.

Summary of Recommendations.

(1) That when death occurs during pregnancy or within four weeks after its termination the fact of pregnancy should be communicated to the registrar along with the fact of death.

(2) That representation be made to the International Committee concerned with the classification of causes of death with a view to securing uniformity of method as well as of nomenclature in compiling official statistics of puerperal deaths.

(3) That every local authority or combination of local authorities administering a scheme of maternity service and child welfare establish an antenatal clinic or antenatal clinics wherever there is a sufficient concentration of population to justify such a measure.

(4) That the antenatal departments at the maternity hospitals should be fully organised and provided with sufficient accommodation for observation, treatment, and teaching, and that such teaching be made an essential part of the practical work of both medical student and pupil midwife.

(5) That payment of maternity benefit be made conditional on the woman engaging a certified midwife or a qualified medical practitioner at least 12 weeks before the date of the normal term of delivery.

(6) That every local authority or combination of local authorities administering a scheme of maternity service and child welfare provide facilities for the testing of specimens of urine, and that where practicable this provision be made through the antenatal clinics.

(7) That local authorities should extend the assistance given to midwives by guaranteeing a minimum income to those whom they regard as satisfactory, and who depend on their earnings for a livelihood.

(8) That local authorities consider the desirability of paying a modified fee to midwives in respect of any cases lost to them by transfer to clinics and hospitals.

(9) That amendment of the Midwives (Scotland) Act be considered, with a view to removing the possibility of unqualified midwifery practice.

(10) That local authorities be empowered to furnish on loan sterile outfit and equipment at a reasonable charge, which should be remitted in necessitous cases.

(11) That the Central Midwives Board for Scotland be asked to consider the desirability of amending Rule E 21 so as to provide for the summoning of medical assistance for the repair of all tears of the perineum.

(12) That attendance of the student on antenatal cases should be organised and made compulsory.

(13) That consideration be given to the question of utilising the accommodation available in Poor-law hospitals for maternity cases.

(14) That legislation be considered to make the conduct of maternity homes illegal unless they are registered by the local authority and conducted to their satisfaction.

(15) That every death occurring within four weeks after the termination of pregnancy should be fully investigated by a person designated by the local authority, and the facts communicated to the Scottish Board of Health.

THE NUTRITIVE VALUE OF BREAD MADE FROM STANDARD FLOUR AND WHOLEMEAL FLOUR.

The question as to the nutritive value of bread made from flours of varying degrees of refinement is one which continues to attract the attention of medical officers and the responsible authorities of educational establishments, hospitals, and institutions.

The memory of the pre-war "standard bread" campaign furiously conducted by a daily paper is not forgotten, neither are the many exaggerated claims which were made at the time for the use of "standard" flour. In 1911 Dr. J. M. Hamill, of the Local Government Board, prepared a very interesting and comprehensive report on the nutritive value of bread made from different varieties of wheat flour. He summed up the advantages and disadvantages of using "standard" or "wholemeal" flour, but made no decided pronunciamiento in either direction.

Recently the governors of a well-known boys' public school sent us samples of wholemeal and standard flours and the loaves made from them and asked us to report upon them as regards their nutritive values. On analysis the following results were obtained :—

—	Wholemeal flour.	Wholemeal bread.	Standard flour.	Standard bread.
	Per cent.	Per cent.	Per cent.	Per cent.
Moisture..	15·6	36·0	15·96	34·8
Mineral matter ..	1·8	2·12	0·86	1·58
Phosphates (P_2O_5) in mineral matter	0·36	0·42	0·32	0·31
Fat	1·84	1·5	1·3	1·14
Proteins	10·5	7·8	9·10	7·05
Carbohydrates, starch, &c.	62·4	45·0	70·20	52·40
Matter not acted on by diastase, pepsin, and pancreatin ..	7·9	7·6	2·61	3·02
Energy value expressed as calories per lb.	1434	1047	1530	1155

In many analyses of this description it is customary to record the "crude fibre" figure, but in our opinion this affords little information from the nutritive standpoint, although it is of use in certain circumstances for diagnostic purposes when judging of the milling grades of different flours prepared from the same wheat. We do, however, attach considerable importance to that part of the bread which is unaffected by the enzymic activities of the digestive juices as, under normal conditions, such matter possesses no food value and would pass away in the fæces. Physiologically this residual matter, which consists mainly of the husk of the wheat corn, may be of some importance as it functions as an intestinal irritant and so counters constipation. This residual matter was determined by boiling the flour or bread with water, cooling to 55° C. and adding a sufficiency of malt amylase, the action being allowed to proceed for several hours. This treatment was followed by pepsin and finally by pancreatin, the reaction of the substrate being suitably adjusted for each enzyme. After the pancreatin digestion the residual matter was filtered, washed, dried, and weighed; a control digestion was carried out side by side using similar quantities of malt amylase, pepsin, and pancreatin, and the weight of insoluble matter found deducted from that in the flour or bread. This digestion in vitro is, of course, not identical with that which takes place in the human organism; it is, however, an approximation, and the results obtained are comparable amongst themselves.

The analyses recorded above show that from the food value point of view (calories per lb.) the standard flour bread is superior to the wholemeal. The proteins and mineral matter (including phosphates) are a trifle higher in the wholemeal loaf. The carbohydrates (starch, &c.) are more than 7 per cent. lower and the material resistant to the action of the digestive juices some 4·6 per cent. higher than in the standard flour loaf. On the evidence afforded by analysis alone it appears that of the two loaves the one prepared from standard flour is the better.

Analytical results in the chemistry of foods are not the whole story, and consideration must be given to the physiological and æsthetic standpoints. The physiology of this subject has been closely investigated by the U.S. Department of Agriculture, who reported that according to the results of experiments on man the proportions of digestible protein and the amount of energy actually available to the body were greater in the standard patent flour (straight run) than in the entire (wholemeal) flour. The importance of the æsthetic element in the digestion of food is well known, and it appears to be admitted by physiologists that food which is pleasant in appearance and palatable is digested more readily than if it were consumed in a less interesting form. In this connexion Dr. Hamill points out that due regard should be paid to individual taste in introducing, for example, a wholemeal bread into a dietary to replace a white bread, lest otherwise attempts at improving the diet may be rendered nugatory. From the same point of view an agreeable or characteristic flavour in bread, such as the "milky" flavour imparted by the germ, may have a distinct dietetic value.

A diet consisting wholly of bread is clearly undesirable, and even if the claims made for the dietetic value of offal (germ, husk, &c.) be admitted, the presence of offal in bread would only diminish and not abolish the monotony of a bread diet. If bread is supplemented with such other foods as usually constitute an average liberal mixed diet the advantages which one variety of bread may possess over another become, for dietetic purposes, practically negligible.

An objection frequently advanced against the use of white bread is the absence from it of the water-soluble vitamin B (anti-neuritic), but this only applies to bread made from patent grade flour which is very white and almost entirely free from husk and germ. The present standard flour is by no means of this high degree of refinement, and such objection therefore does not hold.

We are not of the opinion that the loaves made from either of the flours do the baker any particular credit as their texture is rough and they are both distinctly heavy. They have somewhat of an "institutional" appearance and would not be tolerated in the ordinary private household. This is a matter which could be set right, and in baking processes there must be room for variation in sample.

IRELAND.

(From our own Correspondent.)

The Free State Local Government Bill.

A further study of the Local Government Bill, 1924, of which a brief summary was published in The Lancet last week, strengthens the opinion that as far as the public health is concerned the principles of the Bill are sound.

Pensions for Medical Officers.—On the other hand, it has become clear that the conditions regarding pensions tend to put medical officers in a definitely worse position than heretofore. The Bill proposes to repeal Section 8 of the Local Government (Ireland) Act, 1919, which gave medical officers, under certain conditions, the right to a pension, as contrasted with the grant of a pension as an act of grace. Further, it is proposed to repeal all previous enactments dealing with pensions and superannuation. Under these enactments a medical officer was entitled, if granted a pension, to have a number of years added to his service in computing the amount of his pension. The present Bill contains no such provision.

Control of Medical Education and Registration.—One harmless phrase in the Bill has given rise to misunderstanding and questioning. In the recital of the duties of the Minister of Local Government, in his capacity as Minister of Public Health, there is included "the training of persons for health services." It has been suggested, among others, by the medical correspondent of the *Morning Post*, that this foreshadows the intention of the Minister to control medical education and registration. The entire paragraph in which the phrase occurs, however, is taken, almost verbatim, and the particular phrase verbatim, from the Ministry of Health Act, 1919, in which similar recitals are made of the powers and duties of the Minister of Health for England, and of the Chief Secretary as Minister of Health for Ireland. The Free State Minister, in fact, is only demanding for himself the same powers and duties as belonged to his predecessor, the Chief Secretary for Ireland. The exact meaning of the words has never been made clear, but it is presumed that the reference is to the training of sanitary inspectors and other such officials.

Proposed Abolition of Rural District Councils.—The Bill has received much opposition in the second reading debate in the Dail, the opposition being chiefly directed to the proposed abolition of rural district councils. There was no hostile criticism of the sections dealing with public health, and they received the warm support of Sir James Craig and others. So strong was the criticism, however, that President Cosgrave declared that after taking the second reading he would allow the Bill to rest until he had received the report of a commission to be set up to inquire into the whole machinery of local government. This means that the Bill cannot reach any further stages for several months. One may hope that in the meantime the Minister may be persuaded to prune it of some of its weaknesses.

The General Medical Council and the Free State.

Sir Donald MacAlister's statement as to the present legal relations between the General Council and the Irish Free State has come unexpectedly to the profession in Ireland, and has given rise to a good deal of panicky talk in the newspapers. It was always understood that the Government of the Irish Free State might at any time desire to take under its control the education and discipline of the medical profession, but it was not anticipated that, without the Free State Government making any move, any technical point would arise to interfere with the present status. So far from making any move in the matter the legislature of the Free State has in its constitution continued all Acts previously in force, including the Medical Acts. It is true that if it were made impossible for medical men qualified in Ireland to obtain access to the General Register, the Irish schools would be gravely damaged.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE Berlin Congress recently held under the presidency of Prof. H. Braun, of Zwickau, was well attended. The first official subject of discussion was the development of

The Surgical Treatment of the Organs of the Thorax,

the introductory address being given by Prof. F. Sauerbruch, of Munich. He said that the majority of surgeons have now adopted the over-pressure procedure in operations within the thorax. Concerning the individual operations, he stated that lesions of the heart, especially from gunshot wounds show a great mortality; sutures of the heart for injuries had hitherto not been very successful. Cardiac troubles caused by compression either by growths or by infundibular thorax have been successfully operated on by removal of the growth or by resection of the ribs or the sternum. Hæmorrhage of the pericardium has been cured by puncture of the pericardium or by pericardiotomy. Great advance has been made in the surgical treatment of the œsophagus; in impermeable stricture of the œsophagus plastic operations are generally adopted; in cardiospasm Heller's operation is now the best method. In cancer of the œsophagus the operation in two stages with the placing of the stomach into the thorax has been successful. He had himself succeeded in curing two diverticulæ of the œsophagus which had perforated into the lungs. The old rule to perform at once resection of a rib in cases of empyema had been abandoned owing to experience gained in recent epidemics of influenza where numerous cases in children and in adult persons had been successfully treated by plain puncture. Cases combined with gangrene of the lungs must, however, be operated on at once by large incisions. Old empyemata must be treated by the exhausting procedure designed by Pertes before a thoracoplasty is considered. The greatest progress has been made in operations upon the lungs. Of 71 cases of bullets in the lungs operated on by the author only three have died. Freund's chondrotomy in emphysema has only a very restricted indication. In bronchiectasis resection of the respective lobe has been successful, as of 11 cases 5 were cured and 3 died. In tuberculosis of the lung resection of the first to the eleventh rib by a paravertebral incision under local anæsthesia was successful, as one-third of the patients suffering from cavities could be cured in this way, a cure meaning that the patients had during four years afterwards no sputum and had resumed work. The mortality from the operation itself is 1 per cent., but 24 per cent. by spread of the tuberculosis to the other lung or by defective expectoration. He had operated on 700 patients in this way. The operation was preferable to artificial pneumothorax. In the course of the discussion Prof. Kirschner, of Königsberg, mentioned a case where after an operation for hernia an embolus had occurred; the patient was thereupon operated on at once after Trendelenburg's method by laying open the pericardium and the pulmonary artery, from which an embolus 17 cm. long was removed. The patient recovered and was shown at the Congress. Prof. Kümmel, of Hamburg, spoke on the cure of bronchial asthma by resection of the sympathetic nerve. The operation is indicated only in cases where the cause of the disease is suggested to be a pathological condition of the nerve. The nerve, together with the ganglion stellatum and the ganglion thoracicum, must be removed first on one side and when the attacks continue on the other side too. He had cured three cases by unilateral and four cases by bilateral operation; one case was unsuccessful and one patient died.

The second official subject for discussion was the

Operative Treatment of Fracture.

The introductory address was read by Prof. König, of Würzburg. According to him, operation is indicated in fractures accompanied by lesions of the soft tissues when the ends of the broken bones lie open; in fractures within or in the neighbourhood of joints; in fractures of the patella and the humerus; in fractures of the calcaneus, the trochanter, and other points of insertion of muscles, and in fractures of the forearm with strong dislocation. The operation ought to be performed as early as the end of the first week after the accident. Narcosis can often be dispensed with. Fixation can be obtained sometimes by plain impaction of the bones; sometimes pinning becomes necessary. Sutures with wire are to be recommended. Lane's splints are useful for fixation, and after fixation suture of the muscles and of the skin must finally be performed. Movements must be made very early; in fractures of the patella as soon as a week after the operation. The functional results were encouraging, although the healing process is slower than without an open operation. Stiffness of the joints has occurred in the speaker's cases in aged patients, but never in young ones. Prof. Steinmann, of Berne, stated that he had had bad results in operations of fractures of the femur, the mortality being 30 per cent.; he spoke in favour of extension by pins.

The third official theme concerned the

Transfusion of Blood,

the discussion being opened by Prof. Küttner, of Breslau. He discussed the different methods, direct transfusion by anastomosis of the artery of the donor with the vein of the patient, and indirect transfusion of blood with an addition of 0·2 per cent. of citrate of sodium. By the latter method blood may be preserved for four weeks, a circumstance which had proved very useful during the war. He discussed blood groups and methods of testing them. The principal indication for transfusion was acute hæmorrhage; in chronic hæmorrhage it not only restored the quantity of blood but also acted as a styptic. Good results were obtained by transfusion in cholæmia and in pernicious anæmia; in leukæmia, however, the results were doubtful, as also in septic processes and in cachexia. In poisoning with carbon monoxide and coal-gas, in pellagra, in melæna of newly-born children the results were satisfactory, but in hæmorrhage from enteric fever, in Werlhof's disease, in uræmia, and in eclampsia the results were not encouraging. In hæmophilia the anastomosis between donor and patient was the specific treatment, and cannot be supplanted by indirect transfusion of blood with a citrate of sodium solution. In relapses the proceeding might be repeated without harm. In the discussion Prof. Anschütz, of Kiel, drew attention to the favourable action of the pre-operative transfusion as a method of improving the resistance of the patients. Dr. Bätzner, of Berlin, reported experiments carried out by him by which it was shown that the cause of death from hæmorrhage was not the loss of blood itself, but an intoxication produced by an insufficient combustion of toxic products. By transfusion the product of toxic substances was diminished.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sydenham Celebration.

IN his address on Thomas Sydenham, delivered before the French Academy of Medicine, Prof. A. Chauffard gave a scholarly account of the life and works of the great English physician, of which the following is a very brief résumé. Thomas Sydenham was born on Sept. 10th, 1624, at Wynford Eagle, and passed his youth in the troublous times of Royalist and Parliamentary dissensions. The Sydenham family were staunch supporters of Cromwell. At the age of 18 Thomas Sydenham went to Oxford University, but political discords played havoc with his studies, and though he qualified Bachelor of Medicine in 1648, as the Civil Wars followed each other he was by turns student and Roundhead captain. In 1655 he married, and the following year set up in medical practice in Westminster. In 1659 Sydenham visited the Faculty of Montpelier, where he studied under a physician highly renowned at that time, Barbeyrac, an enthusiast for the school of Hippocrates which was followed at Montpelier, while Paris adhered to Galen. In 1661 he returned to work in London, three years before the Great Plague broke out. Sydenham's action of leaving the "charnel house which London became" was the only regrettable incident of a noble life. At this time Sydenham produced the first of his works, the "Methodus Curandi Febris." "In this book," said Prof. Chauffard, "which is so personal a record, there are no quotations from authors, no burdens of erudition, nothing but clinical facts . . . this is the pure Hippocratic tradition." The fevers which Sydenham observed were probably typhoid, typhus, and malaria, rampant in the London of those days. In addition, Sydenham's description of small-pox has remained a classic.

In 1683 appeared what is perhaps his most famous work, the treatise on gout and dropsy, and three years later he described that condition since known as Sydenham's chorea. In it conciseness the description is perfect, and the work in which it was published was Sydenham's last, for he ended the book by declaring that he had told all he knew concerning the treatment of diseases. "Is it not touching," comments Prof. Chauffard, "to see this great observer himself recognising and admitting that he had reached the limits of his knowledge, and entering thus into the silence and the serenity of a man who, after long labour, considers his task as finished?" Sydenham died on Dec. 29th, 1689, worn out by the two enemies which had long harassed him—gout and gravel. His own symptoms and sufferings from renal calculus he depicted with striking exactitude.

Such was the life of Sydenham, chequered in youth by the civil discords of the times, but later a record of calm, unbroken work and devotion. He sought neither honours, nor public service, nor a professorial chair. Nor did he even hold a hospital appointment: he knew no other ambition than to examine his patients thoroughly, to tend them with his best skill, and to give the results of his observations to the medical public. Before everything, he was a great practitioner. Prof. Chauffard then discussed in greater detail the principal features of Sydenham's work, and showed how, both in methods of observation and in therapeutics, Sydenham "taught medical men to dare to think for themselves."

Prophylaxis Against Measles.

Measles is particularly serious in the case of infants, as more than three-quarters of its victims are children who have not reached their second year, especially in the poor quarters of towns where the hygienic conditions are defective. The prophylactic injection of convalescent serum has been found, if not to give complete protection against measles, at least definitely to modify the disease. Dr. Robert Debré, who is trying to bring this method into widespread use, recently indicated to the Academy of Medicine the lines on which a centre might be organised to collect, prepare, and control the serum of convalescents. This centre would work in conjunction with the hospital services. Dr. Debré proposed that prophylactic centres against measles should be created throughout France, with the object of collecting the serum, of controlling its effectivity, and distributing the necessary doses. He suggested that this method might equally well be adopted in a fight against whooping-cough.

NOTES FROM THE U.S.A.

(FROM A CORRESPONDENT.)

IOWA STATE MEDICAL SOCIETY: NEED FOR SOLIDARITY.

THE seventy-third annual session of the Iowa State Medical Society was held at Des Moines, Iowa, on May 7th, 8th, and 9th. Dr. Oliver Fay, in his presidential address, spoke of the necessity for solidarity in the medical profession in the face of quackery and also unfair State interference, citing in the latter connexion the success of the profession in Great Britain in the recent panel controversy.

Amongst a number of interesting papers read was one by Dr. Abt, of Chicago, on the

Diseases of Twins.

Referring to the rarity of investigation in this interesting field, Dr. Abt said that since Galton's memorable studies no investigation had been conducted on the pathological aspect of twins. The *British Medical Journal* of 1912 contained a very interesting and suggestive editorial on twinship and fame. The editorial was suggested by the remarks of Dr. Kaiser, of Dresden, who stated that he knew of no famous man who had a twin brother. A similar query had been raised by Simpson in the *Edinburgh Medical Journal* of 1862. Simpson was not aware of a single instance in which a twin had distinguished himself intellectually. The editorial writer took issue with these two gentlemen and went on to show that there were several twin brothers who had won more or less fame. In attempting to collect information on this subject it was found that no records of morbidity or mortality in twins were available. According to Grasst, multiple pregnancies are neither atavistic nor the result of variation, but simply indicate excess of natural fertility. Newman pointed out the disadvantages of twinning by saying that when two or more fœtuses come to occupy the space usually filled by one, there is crowding and competition for common food-supply or placental site. On this account, of uniovular twins, one—the successful one—may be strong and healthy at birth, the other weak and delicate physically and defective mentally. Congenital malformations are fairly common and usually occur in both twins. Prematurity, for obvious reasons, is relatively frequent in twin pregnancies, so that rickets and kindred disorders are of high incidence. Occasionally one of the twins will succumb and the other remain free or develop the disease later. Alfred Hess states that twins—even full-time —have a special tendency to develop rickets. The mental affections of twins do not differ in form or frequency from those of other individuals, but when insanity develops in both twins the form is nearly always the same. There is often a marked difference shown in resistance to infection. Cases are reported where one of the twins showed congenital syphilis, while the other remained free. In regard to mortality, twins are said to have 13 times less chance to live than single newborn infants. After the fifth year the mortality of twins and non-twins is the same. In conclusion, Dr. Abt drew comparisons between himself and his twin brother.

Dr. Hubert A. Royster, of Rayleigh, North Carolina, gave an address on the

Philosophy of Surgery.

The speaker defined the philosophy of surgery as the fine adjustment of the higher instincts upon the *n*th power of surgical art and science. Above other men the surgeon needed the philosophical spirit. All great art represented something that it saw or believed in. How true this was of surgery! It saw what was actually accomplished—and more—what was intended; it believed in what was to be done. It was difficult to conceive of surgery without vision and faith. Not all the best of surgery was accomplished in the largest clinics or by the busiest operators. The surgeon who counts was not always the one who was doing the most work, but the one who was doing the most of the best work. In every true surgeon there was a constant effort to strike a proper balance between judgment and technique, between diagnosis and management, between pathology and performance. The sum of our philosophy, he said, was this: The surgeon would do well to bear in mind that his mission was to restore if he could, and only to destroy if he must; that his duty was to keep sweet in the midst of both success and of disaster, of praise and of censure—and the smaller his habitation, the sweeter he should keep; that moral courage was a more precious asset than physical prowess, and that it often required more bravery to desist from an operation than to proceed with it; that sordid commercialism in any degree would corrupt his professional life and poison his soul, be it the buying and selling of patients or other debasing financial practices; that it was his privilege to perfect himself in the science and art of his calling to the end that he might be of use both in knowing and in doing, not omitting to tune his conscience and his judgment to the highest pitch; that individual thinking combined with an understanding and a concurring spirit would bring the largest benefit; and that he must carry on his career in his own way, emulating, not imitating, the best he found in others who had passed along the road.

Dr. Emil Mayer, of New York City, read a paper on the study of

Affections of the Nose and Throat

with special reference to the diagnosis of affections in other parts of the body. The speaker discussed a number of conditions of the nose and throat giving rise to generalised symptoms which yield to simple treatment of the cause. Thus, in cases of persistent coughing without râles, examination of the nose and throat should always be resorted to, when an elongated uvula, foreign body in the ear, or other defect will not infrequently be found, the removal of which leads to cure of the condition. In regard to the diagnosis of generalised disease, tuberculosis often appears primarily in the nose and throat, and may sometimes be noticed here before it would otherwise be suspected. Small canary-yellow exudates appearing in the mouth, palate, tongue, cheeks, or lip are not infrequently the earliest sign of this disease. Inter-arytenoid thickening is another early sign. Primary syphilis may occur on the lip, tongue, or tonsil, while Koplik's spots, as is well-known, afford the earliest diagnostic sign of measles. A number of other conditions were mentioned in which the diagnosis is made from nose and throat examination.

MALVERN AS A HEALTH RESORT.

THE pleasant group of townships known as Malvern, terraced on the lower eastern slopes of the Malvern heights, was the object of a pilgrimage by representatives of the daily and weekly press of the country during the last week-end, who, as guests of the town and of the Great Western Railway Company, examined the claims of this famous Worcestershire residential district to a high place in the ranks of English health resorts.

Malvern's fame, which was as high in the latter part of the last century as it is now, when many other centres compete with it, rests on a triple basis—its situation, its climate, and its waters. The waters have been recognised for nearly 300 years as being of exceptional purity, which recent analysis, showing an almost entire freedom from organic matter, fully confirms. Their value lies in their very purity and in their non-mineral character, which renders them applicable in gout and the rheumatic diathesis. The water bubbles from springs situated above the town, and a short but healthful climb brings the patient to the Pump Rooms of St. Ann's Well, which was built over 50 years ago. It is, perhaps, in its situation and climate that the resort makes its strongest appeal to the seeker after health and quiet. The chief advantages of Malvern result from its famous position on the gentle slopes of an easily accessible range of hills which, while it extends over nine miles and reaches at the highest point to 1400 feet above sea-level, is provided with good roads and easy hill paths, offering opportunities for every degree of pedestrian activity. Thus Malvern may well be regarded as a hill station especially adapted for cardiac conditions requiring graded exercises, and for convalescence from acute conditions. The moderate elevation of Malvern suffices to raise it above many of the fogs which so often cover the plains or river valleys of England in the autumn and winter, and during the last week-end, when the flooded Severn, Avon, and Teme, following the furious rains of Saturday and Sunday, spread desolation over the plains, inundated the fields, and plunged the city of Worcester, eight miles away, into darkness and inactivity, Malvern escaped unscathed. Indeed, the rain did not deter some of the more active of the inspecting party from climbing to the Herefordshire Beacon, round the top of which the ancient British camp extends its triple line of entrenchments, and on Monday morning, when the sun shone again, a drive over the rapidly drying roads of the Heights, through a fresh and stimulating air, offered a panorama on the one side of "county upon county of rich sylvan England, mansioned, abbeyed, towered, spired, castled," and to the westward the mountains of Wales rose in the distance.

Apart from its bracing air and large measure of sunshine, Malvern affords good hydro- and electrotherapeutic facilities. The following baths, among other kinds, may be obtained: Shower, spray, sitz, brine, soda, sulphur, pine extract, Nauheim, spinal wave and ascending douches; Russian vapour, radiant heat, electric light. Plombières lavage, massage and electrical treatment of various kinds may be had at the several special establishments. Malvern Hydropathic was the first institution for hydrotherapy to be built in England, and has kept well abreast with modern developments. The town has at present a scheme in hand for the provision of a swimming-bath and hot baths supplied with Malvern hill waters. Ample provision is made for various sports; the tennis courts at Manor Park are particularly fine, there is a good golf course, and three packs of hounds hunt in the neighbourhood.

It is such British health resorts as Malvern that offer to the visitor the charm of restful days in ideal climatic conditions that may be sought in vain among the more populous and the gayer spas, not only of the continent, but also of Britain.

SIR MALCOLM MORRIS MEMORIAL FUND.

THE hon. secretary of the committee, Dr. Howard Mummery, reports a very satisfactory response to the appeal published on May 10th in our columns for the above Fund and there is every hope that its objects will be achieved. Subscriptions have already been received from the following :—

Lady Alexander.

Dr. R. A. Bolam, O.B.E.; Botolph Printing Works; Mr. Philip Bright; British Humane Association; Dame Sidney Browne, G.B.E., R.R.C.; Miss M. M. Brumhead, Mr. R. Byers, J.P.

Sir W. Watson Cheyne, Bart., K.C.M.G., C.B., F.R.S.; Mr. J. F. Christie; Miss Clarke; Mr. Ernest Clarke, M.D., F.R.C.S.; Dr. Alfred Cox, O.B.E.; Mrs. Latham Cox; Sir Anderson Critchett, Bart., K.C.V.O., F.R.C.S.

Dr. T. W. A. Daman; Major Leonard Darwin; Mr. S. Ernest Dore, M.D., F.R.C.P.; Sir Arthur Conan Doyle.

Prof. John Eyre, M.D., M.S.

"A Friend"; Mrs. Fordham.

Mrs. S. A. Gamble; Mr. S. M. Gluckstein; Miss M. O. Gordon; Mrs. A. E. Gosnell.

Miss M. Hardman; Sir Thomas Horder, Bart., M.D., F.R.C.P.; Miss V. G. Hort; Miss C. Hosack; Dr. F. B. Hulke; Mr. W. W. Hutchings.

Mr. J. C. Isard.

The Very Rev. Dean Kirkpatrick.

The Lancet; Prof. F. S. Langmead; Mr. J. Spedan Lewis.

Dr. and Mrs. F. C. Madden; Mr. Arthur R. Moro; Dr. S. G. Mostyn; Dr. N. Howard Mummery.

Mrs. Olive; Mrs. C. Owen.

Mr. C. F. Rilot, M.R.C.S., L.D.S.; Dr. Adeline Roberts.

Dr. Mary Scharlieb; Scholastic, Clerical, and Medical Association; Dr. and Mrs. Alexander Scott; the Countess of Shaftesbury; Mr. A. Allan Shand; Mr. W. H. Shrubsole; Miss F. Smith; Sir Arthur and Lady Spurgeon; Dr. Horace Sworder.

Major-General Sir Reginald A. J. Talbot, K.C.B.; Miss L. Thevenard; Sir StClair Thomson, M.D., F.R.C.S.; Miss StClair Thomson; Mrs. M. R. Torrey; Mr. E. B. Turner, F.R.C.S.

Miss Jane Walker, M.D.; Sir Arthur Whinney, K.B.E.; Sir William H. Willcox, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P.; Mrs. F. B. M. Williams.

Mr. Thomas Young.

The total to date is £252 13*s*. Further subscriptions will be gratefully acknowledged if forwarded to the Hon. Treasurers, "Sir Malcolm Morris Memorial Fund," at 12, Stratford-place, London, W. 1.

"Audi alteram partem."

VOLUNTARY HOSPITALS COMMISSION: EXTENDED INQUIRY.

To the Editor of THE LANCET.

SIR,—In the summer of 1922 the Voluntary Hospitals Commission decided to convene a conference of representatives of local voluntary hospitals committees, which was held in July at the Ministry of Health. The conference was very well attended, and I think representatives from practically every voluntary hospital committee in England and Wales—and many of those in Scotland—were present. The discussions which took place were of great value to the members of the Voluntary Hospitals Commission, whose main pre-occupation at that time was the distribution of the Government grant of £500,000 in aid of the deficits on the maintenance accounts of the voluntary hospitals. That task has now been accomplished. Since that date a fresh, and perhaps even more difficult, task has been placed upon the Commission by the present Government. Fresh terms of reference have been given to them which are as follows: "The Voluntary Hospitals Commission are requested to inquire into and report upon the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it."

To obtain sufficient data on which to base a useful report will require considerable investigation. The Commission have already sent out a questionnaire in regard to matters on which it occurs to them that information should be afforded, but it is felt that it would be of the utmost value if a full discussion could take place with the representatives of the local voluntary hospitals committees as to the best methods by which this investigation could be carried out. A conference will be held at the Ministry of Health on June 18th at 10.30 A.M. It is earnestly hoped that all local hospital committees will be officially represented, but in addition all members of committees will be very welcome if they care to attend. I may add that although the new terms of reference and the best method of giving effect to them will be the most important subject of discussion, some of the committees have put down other matters which they desire to have considered and these will also be discussed.

I am, Sir, yours faithfully,
ONSLOW,
Chairman.

Whitehall, S.W., May 30th, 1924.

"INDUCTION" OR "CAUSE" OF CANCER.

To the Editor of THE LANCET.

SIR,—It will be well to realise that factors that induce carcinoma belong to quite a different category from those that cause it. So many writers are confusing the two processes by describing them under the one term, "cause," as if the factors of induction were the same as those of causation. They are not; for example, the slightest push may induce a ball to roll downhill. The push only induces the ball to roll. The precise nature of the various factors that cause a ball to roll downhill are subjects of acute controversy amongst the profoundest intellects of our time. When discussing carcinoma, if certainty could be arrived at as to the actual factors that induce it, no doubt a great advance would be made in our conception of the disease. If certainty could be arrived at as to the actual cause of carcinoma, the problem "What is Life?" would be solved. It will be well to recognise that the induction and cause of carcinoma are quite separate processes.

I am, Sir, yours faithfully,
G. LENTHAL CHEATLE.

Harley-street, W., May 31st, 1924.

TOXIC EFFECTS OF LOCAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Dr. Dan McKenzie deserves our thanks for setting forth his method of using pure cocaine hydrochloride powder mixed with sufficient adrenalin solution to form a mud or paste for direct application to the nasal mucosa for producing local anæsthesia. Further, that thus applied he habitually uses as much as 4 to 6 g. of cocaine for each case, and never has he had one single case of cocaine poisoning. Assuming that this is the cocaine paste referred to in the report of the committee of the American Medical Association which they recommend "should never be used," Dr. McKenzie's letter is a timely and authoritative protest against such sweeping general statements.

Yet it seems curious to find that Dr. McKenzie goes on to lay down "a rule that cocaine, whether in powder or in solution, should never be employed without adrenalin." The need for caution in the exhibition of all local anæsthetics must be borne in mind, nevertheless many of Dr. McKenzie's colleagues regard it as one of the unrivalled advantages of cocaine over all other local surface anæsthetics that cocaine may be used for light anæsthesia of the nasal mucosa without the disadvantages accruing from the application of adrenalin. Probably Dr. McKenzie referred to the use of strong cocaine application for pronounced degrees of anæsthesia, but if this be so, it only emphasises the need for care in avoiding such generalisations as Dr. McKenzie himself condemns and which tend to hinder rather than help us in arriving at sound conclusions.

I am, Sir, yours faithfully,
PATRICK WATSON-WILLIAMS.
Clifton, Bristol, June 2nd, 1924.

MALARIAL TREATMENT OF GENERAL PARALYSIS.

To the Editor of THE LANCET.

SIR,—In your leading article of May 24th it was stated that ". . . we are at a loss to understand how the cerebral sclerosis and the degeneration of the nervous tissue can be permanently affected" by the malarial treatment of general paralysis. It is, however, unlikely that the lesions are affected.

In a limited experience of about 30 general paralytics treated with malaria, I have noticed that the physical signs known to depend upon a lesion of a definite locality of the nervous system, such as the Argyll Robertson pupil and the loss of ankle-jerks, remain the same after treatment as before, although the tremor, the slurring of the speech, and the abnormal mental state may have vanished and the general physical condition greatly improved. So far as I am aware, no reports have been published of the pathological condition of patients treated with malaria who have died of intercurrent disease whilst improving as regards the general paralysis, so it is impossible at present to be sure whether the structural organic lesions of the nervous system are affected. The pathological condition in a case of advanced general paralysis who had been treated with malaria and had subsequently died of the paralysis does not assist us, as the typical appearances of the untreated paralytic would presumably be found as the patient had died from this disease. As regards the macroscopical appearances, I found this to be the case in one such instance. The microscopical examination is not yet completed.

Therefore, if other observers have also found that the physical signs known to be dependent upon organic disease of the nervous system persist after the malarial treatment, it would appear that the destruction of the nervous tissue is not healed, at any rate, as regards the power of functioning. It would be interesting to know what has been found in this connexion at other institutions.

It should be added that although it is possible for a neurone to be functionally deranged without being organically destroyed, as probably occurs in the earlier stages of disseminated sclerosis, presumably this would precede the organic lesion in general paralysis. Therefore this functional derangement would be likely to occur in extremely early cases only, and then probably not as regards all the signs.

I am, Sir, yours faithfully,
G. DE M. RUDOLF.
Claybury Mental Hospital, May 28th, 1924.

GASTRIC AND DUODENAL HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—The paper by Dr. A. F. Hurst in THE LANCET of May 30th contains many useful suggestions for treatment in this serious emergency—e.g., rest, starvation, neutralisation of acid; but washing out the stomach, however skilfully performed, seems to me rather dangerous. In my judgment, however, Dr. Hurst overlooks the one essential fact—that gastric and duodenal ulcers are secondary results of trouble in the ileo-cæcal region and in the large intestine. This is a commonplace of medicine to those who are conversant with Sir Arbuthnot Lane's doctrine of stasis, but even those who have not yet wholly accepted stasis agree that gastric and duodenal ulcers are secondary to mischief lower down. I have searched Dr. Hurst's paper in vain for any sign of a recognition of this fact so essential to effective treatment.

Surely the first step, after putting the patient to bed, is the evacuation of the intestines by enemata. I venture to assert that this one step is more effective in arresting gastric or duodenal hæmorrhage than all the local measures advocated by Dr. Hurst. He draws an analogy between the stomach and the uterus. The analogy is partially true of the healthy stomach which *does* contract when empty, and does reduce its lumen to a small size, though never to zero like the uterus. My experience with bismuth and X rays in gastric ulcer shows that the stomach is invariably dilated and dropped. It does not contract when empty, and cannot until a long course of treatment (for three weeks or more) by rest in bed, enemata, &c., has overcome the duodenal distension and pyloric spasm which are keeping the lumen of the stomach widely open.

I am, Sir, yours faithfully,
ALFRED C. JORDAN.
Upper Wimpole-street, W., June 2nd, 1924.

CRIMINAL RESPONSIBILITY OF THE INSANE.

To the Editor of THE LANCET.

SIR,—Will you allow me to correct an error that has crept into your otherwise excellent summary[1] of my remarks at the Section of Psychiatry of the Royal Society of Medicine? I am reported as saying that "a great point about such impulsive states as epileptic insanity and puerperal mania was, not that the obsessions constituted irresistible impulses, but impulses resistible which had not been resisted."

I am afraid these words must have puzzled your readers. They suggest that I propounded the view that the violent impulsive actions of epileptic and puerperal insanity are controllable by penal sanctions—which is absurd. What I did say was that where, as in the case of epilepsy and puerperal mania, the degree of impulsive action is high enough to be described as "irresistible," it is difficult to say that the patient knows or appreciates the nature and quality of the act. Consequently such cases are quite capable of being brought within the law as stated in the McNaghten rules. There is nothing novel in that point. It was made 50 years ago by Fitzjames Stephen.

On the other hand, in regard to such states as are merely obsessional, I said that it was impossible on legal or logical grounds to describe the impulses to which they gave rise as "irresistible." We know that such impulses are powerful, but we also know that they can be and are resisted. There is nothing new in that either. Mercier and many others have pointed it out. What I wanted to emphasise was that the doctrine of "irresistible impulse" was of no value, for it could not properly be applied to any case that is not within the four corners of the existing law. I am, Sir, yours faithfully,

Donald Carswell.

New-square, Lincoln's Inn, May 26th, 1924.

A COUNTY VENEREAL DISEASES SCHEME.

To the Editor of The Lancet.

Sir,—Being interested in venereal diseases, and in charge of a municipal clinic, I read the article on this subject by Dr. J. J. Butterworth in your issue of May 24th. I was, however, surprised to find his laborious piece of statistical work lacking in important details, and so rendering his Tables II., III. (B) (C) misleading and in part valueless. Dr. Butterworth divides the attendances at the V.D. clinic into (1) those who complete the full course of treatment, and (2) those who ceased attending before completion of treatment. Unfortunately, he does not give the slightest indication of what "the full course of treatment" is. Does he mean one course of eight or ten injections or does he mean several? In the headings of his tables he speaks of "final tests as to cure," and "persons discharged from the clinic after completion of treatment and observation." What does this mean in dealing with syphilis and soft chancre? How long has he kept the patients under observation?

Take syphilis: When does he have complete confidence "to discharge patients from the clinic" which is tantamount to discharging them as cured? Is he satisfied with a negative blood Wassermann for 3, 6, 12 months or more? How long does he keep his soft sores under observation? Without some reasonable information on these points, some of his tables as they stand are, to my mind, quite valueless to others, and I feel it is a pity he has spoiled part of his labours by neglecting what to me are essential details in work of this kind.

I am, Sir, yours faithfully,

W. Herbert Brown.

Glasgow, May 29th, 1924.

MEDICAL TREATMENT OF CATARACT.

To the Editor of The Lancet.

Sir,—I have read with much interest the article by Dr. Inglis Taylor on the above subject, as I have been myself for several years in the habit of using medical treatment for incipient senile cataract. Where the patient can come to me regularly I use subconjunctival injections of cyanide of mercury, 1 in 5000, with 4 per cent. solution of sodium chloride, injected about once a week for about three months. When the patient lives at a distance I prescribe a collyrium of pot. iod. and sod. iod. each ʒiiss. to a pint of water to be used for five minutes twice a day; vasogen of iodine to be rubbed round the eyes at bed-time.

I hope to tabulate my results some day, but not having time to do so just now I will give briefly the result of my first case treated by the subconjunctival method, the result of this case being typical of many others and being apparently permanent.

Mrs. T., aged 50, consulted me on April 27th, 1918, complaining that the sight of her left eye had been failing for a year. Vision was 6/12 (2), not improved by glasses. Examination revealed an incipient cortical cataract. I gave her a subconjunctival injection once a week. By June 12th vision had improved to 6/9 (4), and by August 28th, when I ceased injecting, it was 6/6 (5), improved to 6/5 (3) by −0·50 spher. Now, after nearly six years, the vision remains the same.

With the pot. iod. treatment the results were good, but not so striking as with the subconjunctival injections.—I am, Sir, yours faithfully,

Seaghan P. MacEnri.

Averard, Galway, May 27th, 1924.

THE TERM "HÆMOCHROMOGEN."

To the Editor of The Lancet.

Sir,—Some years ago in a joint paper (*Biochem. Jour.*, xiii., 1919, 195), Dr. O. Rosenheim and I entered a protest against the continued use of the term hæmochromogen as a synonym for reduced hæmatin. The former word, introduced by Hoppe-Seyler, is illogical—for the substance is not a chromogen; and unnecessary—for Stokes's original name correctly describes it. This simplification of nomenclature was originally suggested on behalf of students, but Prof. A. V. Hill's lecture (The Lancet, May 17th, p. 994), where he confuses it with hæmatoporphyrin, is a demonstration that these long words are perplexing to teachers also. Many who read the original lecture may not see the correction in your issue of to-day.—I am, Sir, yours faithfully,

W. D. Halliburton.

Marylebone-road, London, N.W., May 31st, 1924.

VACCINE FOR ENCEPHALITIS LETHARGICA.

To the Editor of The Lancet.

Sir,—It may be still open to question whether or no encephalitis is simply "influenzal" meningitis, but one clinical fact that makes me believe this is that in the one instance in which I used an "influenza" compound vaccine, out of three cases under my direct observation since 1918, the "apparent" result was very striking, and the patient made a good recovery. The patient herself is convinced that the vaccine was the factor that turned the scale in her favour. The formula was that used in the R.A.M.C. during the 1918 "influenza" plague, and in the dearth of any other specific remedy it is surely worth while trying this vaccine in other cases.

I am, Sir, yours faithfully,

Leamington Spa, May 27th, 1924. J. Pirie, M.D.

TARTAR EMETIC IN BILHARZIASIS.

To the Editor of The Lancet.

Sir,—Mr. J. E. R. McDonagh alleges inaccuracy in the footnote on p. 1071 (The Lancet, May 24th). There is none whatever. With regard to priority for first having given the injections, readers of The Lancet interested in the matter are referred to the *Journal of Tropical Medicine and Hygiene* for June 15th, 1923. In the article entitled the Antimony Treatment of Bilharziasis will be found all I wish to write about my share in the discovery or re-discovery of the remedy.

I am, Sir, yours faithfully,

J. B. Christopherson.

Devonshire-place, W., May 31st, 1924.

ST. MONICA HOME OF REST, BRISTOL.

To the Editor of The Lancet.

Sir,—I am anxious to bring to the notice of any persons who may be described as gentlefolk in poor circumstances the benefits which are intended for them by my late husband, Mr. H. H. Wills, the founder of this institution, and should be very grateful if you would enable me to do this through the medium of your columns.

The object of the St. Monica Home of Rest, Westbury-on-Trym, Bristol, is to receive as inmates gentlefolk who are members of the Church of England, suffering from certain chronic or incurable ailments, being in needy circumstances and having led honourable lives. The council of the home have also power to give financial assistance to a limited number of persons who cannot be accepted as inmates. Preference will be given, in both cases, to those having family or residential associations with the city of Bristol or the counties of Somerset, Gloucester, and Wilts. Persons mentally afflicted, epileptics, sufferers from an infectious or contagious complaint, or from cancer or other forms of malignant disease are not eligible for admission to the home. Persons mentally afflicted, beneficiaries of other charitable institutions —so long as they are in receipt of such benefits—recipients of State aid (other than earned pensions) or of assistance from the rates are ineligible for financial assistance.

The home will probably not be ready for the reception of inmates till the end of this year at the earliest, but, in the meantime, the council are prepared to grant financial assistance to a limited number of qualified persons prior to the completion of the home. All inquiries should be addressed to Mr. W. W. Ward, Merchants' Hall, Bristol, the treasurer of the institution.

I am, Sir, yours faithfully,
MARY MONICA C. WILLS,
President of the Home.
Clifton, Bristol, May 20th, 1924.

THE PSYCHOLOGY OF VERTIGO.

To the Editor of THE LANCET.

SIR,—With reference to some recent correspondence in THE LANCET concerning psycho-analysis, I beg for space to indicate the letter on vertigo by Dr. W. H. B. Stoddart in your issue of May 24th as a striking example of the *argumentum in circulo*, lately proved in the books by Dr. A. Wohlgemuth and Dr. P. McBride to pervade the current literature of psycho-analysis from Freud's works onwards. This letter is a complete circle of dialectic beginning, continuing, and ending exclusively in unverified assumptions.

I am, Sir, yours faithfully,
London, May 28th, 1924. H. BRYAN DONKIN.

To the Editor of THE LANCET.

SIR,—My attention has been directed to a very remarkable contribution towards the much discussed questions of vertigo and sea-sickness by Dr. W. H. B. Stoddart. In my early youth a pious nurse used to tell me that evils such as these were due to the direct intervention of the Prince of Darkness. My medical studies and experience had inclined me to believe that such symptoms might be traced to organs such as the semicircular canals, the cerebellum, possibly also to the cerebrum and stomach. In the light of Dr. Stoddart's letter I am led to reflect that perhaps his psyche and unconscious may be what my old nurse used to designate more shortly "Satan." Such an explanation would at least have the merit of simplicity. Let me recommend your readers after carefully studying Dr. Stoddart's letter to draw their own conclusions.

I am, Sir, yours faithfully,
Harrogate, May 28th, 1924. P. MCBRIDE.

PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—In his useful address on puerperal sepsis, published in your last issue, Mr. Beckwith Whitehouse, under the heading of General Treatment (p. 1095), states :—

> "As I have noted previously, cases occur where the infecting agent is so virulent that the patient is dead almost before treatment can be instituted. I remember one such instance some years ago. I was called to see a primipara, confined 24 hours previously, who had a temperature of 104° F. She was covered with an erythematous rash and died the following morning within 48 hours of the labour. A diplococcus, apparently the pneumococcus, was present in the blood."

All sections interested in clinical and bacteriological diagnosis will agree that the finding of the pneumococcus does not establish the diagnosis of puerperal sepsis. There is strong clinical evidence that a fever in the first 24 hours after childbirth, such as Mr. Whitehouse illustrates, is more consistent with an illness of extraneous origin—e.g., scarlet fever. Until special clinical equipment in hospital has been long and widely in operation doubt must be attachable to every set of statistics and every series of statements.

I am, Sir, yours faithfully,
Liverpool, June 2nd, 1924. HENRY BRIGGS.

To the Editor of THE LANCET.

SIR,—Mr. Beckwith Whitehouse, in his recent paper on puerperal sepsis, refers to observations of mine carried out "at Queen Charlotte's Hospital." I wish to point out that this is an error; all my work on this subject has been carried out at the London Hospital. Regarding his practice of "lightly" curetting the uterus followed by frequent irrigation of the uterine cavity by the Carrel-Dakin method, I am not opposed to it if it can be carried out by an expert early and under ideal conditions. The principle of excising the infected wound area is undoubtedly correct, but I think it is impossible to do this when infection has been present in the uterine cavity more than a day or two; in such cases, therefore, I consider it safer to remove debris with ovum forceps and a swab on a sponge-holder and to sterilise the surface of the uterine cavity with 2 per cent. iodine in spirit. The application of the Carrel-Dakin method afterwards is difficult in a patient who is having rigors, and may cause a good deal of fatigue. Thus, though my methods appear to differ from his, I certainly agree with him in theory. With his experience of the success of intravenous medication I entirely agree.

I am, Sir, yours faithfully,
S. GORDON LUKER.
Park-crescent, W., June 3rd, 1924.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Sub-Lt. G. F. S. Parker is promoted to Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

TERRITORIAL ARMY.

Lt.-Col. A. W. Moore, from Gen. Hosp. List (Supernumerary), to be Lt.-Col., and to commd. the 48th (1st Southern) Casualty Clearing Station.

Capt. A. J. Gibson to be Maj.

Capt. E. S. Stork, having attained the age-limit, is retd., and retains the rank of Capt.

2nd Lt. B. G. Thompson, from Gen. List, T.A., to be Lt.

A. M. Cooke to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. W. S. Forbes to resign his commn. and to retain the rank of Capt.

ROYAL AIR FORCE.

Flight Lt. S. E. Elphick resigns his permanent commission.

MENTIONED IN DESPATCHES.

The names of the undermentioned have been brought to notice for distinguished service during the operations in Waziristan, January, 1922, to April, 1923, by His Excellency General Lord Rawlinson of Trent :—

Royal Army Medical Corps: Lt.-Col. W. M. H. Spiller, Majors A. Irvine-Fortescue and C. H. Stringer, and Capt. B. C. O. Sheridan.

Indian Medical Service: Maj. D. C. V. FitzGerald, Capts. G. M. Moffat, F. R. Thornton, and C. J. Stocker; and Temp. Capt. K. G. Mohile.

MEDICAL STUDENTS AT DROITWICH.—By invitation of the Trustees of the Corbett Estate, who own the brine baths, a party of 45 medical students from Birmingham University visited Droitwich on May 31st in charge of Dr. Douglas Stanley, lecturer in therapeutics at Birmingham University. The party was conducted round the baths by Dr. J. Wilkinson and Dr. F. I. Dawson (the local representatives of the International Society of Medical Hydrology), Dr. M. Campbell, and Dr. C. F. Curtis, and the majority of them enjoyed a dip in the brine swimming-baths. Demonstration was given of the method of administering brine treatment for rheumatic and other systemic conditions.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics for 1923 of eight districts varying in type, the annual health reports of which we have received :—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Dewsbury C.B.	55,424	17·0	14·0	0·8	1·3	3·7	40	83	8·5
Hartlepool B..	21,570	26·4	14·9	1·6	—	4·0	44	108	3·5
Tunbridge Wells B.	4,370	13·9	14·2	1·0	2·1	1·7	27	50	Nil.
Barnstaple R.D.	18,270	16·2	12·1	1·4	1·7	1·0	—	40	3·3
Adwick-le-Street U.D.	13,420	32·7	10·2	0·8	0·4	2·6	—	82	4·5
Bentley-with-Arksey U.D.	14,010	26·9	10·2	1·2	0·8	2·3	—	74	Nil.
Thedwastre R.D. ..	8,480	18·7	14·6	1·3	1·5	—	—	50	6·3
East Stow R.D.	6,465	21·5	9·7	0·9	1·1	—	—	29	Nil.

Dewsbury.

Dr. Oscar M. Holden reports that respiratory diseases play a very prominent part in the causes of death and blames the impurity of the atmosphere in this county borough. In the sanitary inspector's report we read that only 31 observations were made of factory chimneys, and that in 13 instances warning letters were sent where black smoke was emitted for over ten minutes in the hour. It is evident from this that the Dewsbury council only play with the problem of smoke prevention. Dr. Holden records progress in the privy-conversion scheme. During the last four years 1000 privies have been abolished without cost to the corporation. At the end of the year there still remained 1341 privies and 127 pail-closets. Attendances have increased at the maternity and child welfare centres. Dr. Holden considers dried milk far preferable as an infant's food to fluid milk as delivered in towns, and believes that its wider use plays an important part in the reduction of infantile diarrhœa. More of the dried milk was paid for and less given away than in the previous year—" an indication of better employment." Moorlands Hall has been acquired and is to be adapted as a maternity home, and Dr. Holden is hopeful that its use may exert a favourable influence on the very high maternal mortality from child-bearing. A table is given showing that this mortality was 8·9 per 1000 births during the four years 1911–14, 7·2 during 1915–18, and 7·9 during 1919–22.

Housing has continued to occupy attention, and Dr. Holden tells us that the great demand is for houses with a large living room, two large bedrooms, bath-room, and scullery to be let at 5*s.* to 6*s.* per week, and that 500 such would readily find tenants. No doubt they would, but the scheme sounds likely to be a costly one for the rates. Dr. Holden tells us that Dewsbury, according to the Census figures, shows the greatest deficiency of rooms, and the highest proportion of the population living, more than two persons to a room amongst the large towns of Yorkshire. An estimate framed on the former basis showed that 3277 houses were needed at the time of the Census, and that only 182 have been built and occupied since the Census. In this estimate no allowance has been made for " unfit " and worn-out houses and blocks of unhealthy property. About 35 per cent. of all the houses are of the back-to-back type, and there are " not a few " of the worse type—viz., back-to-earth. There is a paucity of midwives in Dewsbury, and resort is had to handywoman help. The corporation have subsidised a former health visitor to practise midwifery in a district where the shortage is keenly felt. During the year a new voluntary nursing association has made a successful beginning.

Hartlepool.

Dr. William McKendrick tells us that a noteworthy event of the year has been the provision of facilities for bowling, tennis, &c., on the town moor, and the opening of the bathing pool, the shortage of accessible recreation grounds and the unsuitability of the shore for bathing purposes having been in the past detrimental to the health of the inhabitants. The Census returns show Hartlepool to have a practically stationary population. Thus, in 1901 it was 22,723; in 1911, 20,615, and in 1921, 20,997. In referring to the high infant mortality rate, a great part of which is due to bronchitis and broncho-pneumonia, Dr. McKendrick says one cannot avoid associating it with the prevailing poverty and vile housing conditions. The prolonged industrial depression, he says, has led to a profound mental depression amongst the poorer classes, and with this there has developed a repulsive callousness. The tuberculosis death-rate and notifications show a tendency to increase, and " this may be the first sign of the undermining effect of poverty on the health of the people." The fish refuse, which used to be sent to sea, is now sent by rail to a manure factory and has become a valuable article. The provision of a public abattoir is under consideration. The only houses built during the year were 30 required to complete the Cleveland-street area municipal scheme. All the houses in this scheme, numbering 121, are now occupied. An inquiry was held in March with regard to another scheme, which has now been sanctioned, and involves the erection of houses for 433 persons. The work of the infant welfare centre suffered during the year from the absence of a medical officer, but is now reviving. The premises are inadequate and the provision of better accommodation is under consideration. The health of the town continues to be menaced by poverty, and the continuance of the trade depression into the fourth year, says Dr. McKendrick, is bound to have dire effects on the rising generation. Vigorous and apparently successful efforts have, however, been made by both statutory and voluntary bodies to combat these effects.

Tunbridge Wells.

Dr. F. C. Linton reports with satisfaction that new premises have been obtained and are being adapted for the work of the chief maternity and child welfare centre, which has lately been carried out under great difficulties at the public health office. In October, public interest in hygiene was successfully aroused by a prize competition in mothercraft among the mothers attending the centres. At the prize-giving a popular health lecture was given by Dr. Elizabeth Sloan Chesser. The isolation hospital still lacks the extension of the administrative block, sanctioned in 1914, and another need is a motor-ambulance to replace the present ambulance for which horses are hired in the town. The school report shows that children with verminous heads do not decrease in numbers, and that eight prosecutions of parents for this offence were undertaken. Mr. Stuart Smith, the school dentist, is making good, the percentage of children treated having risen from 60 in 1922 to 72 in 1923, and this in spite of the fact that a small fee is now charged for treatment. Dr. Linton records a reduction in the number of children with defective vision, and expresses the opinion that this improvement is due to the disappearance of the effects of the defective diet and under-nourishment of the war years. Dr. Linton would like to see an open-air school or class established for physically-defective children. Meals are not provided at the schools, but soup-kitchens are open at several centres during the winter months, which are largely used by the school-children. Instruction in swimming is provided at the open-air baths, and special terms are granted for the admission of the school-children both to the open-air and indoor swimming baths.

Barnstaple.

Dr. J. R. Harper reports a mild outbreak of epidemic jaundice among the children attending Tawstock school. Influenza became prevalent at the end of the year and spread widely over the rural district during the first quarter of 1924. One of the needs mentioned is the provision of public conveniences for day trippers near the sands of Instow, Braunton, Combe Martin, and Woolacombe.

Adwick-le-Street and Bentley-with-Arksey.

Dr. A. B. Dunne reports outbreaks of small-pox in both these urban districts. In Adwick the first case was notified on Feb. 13th, and 30 cases were notified up to Dec. 31st. There was a gap from May 7th to Sept. 22nd, after which Dr. Dunne thinks infection was reintroduced from outside. Infant vaccination had largely fallen into desuetude in the Doncaster Poor-law area, but was stimulated by the outbreak. There were 717 primary successful vaccinations in 1923 as compared with 111 in 1922. In the Bentley district 77 cases were notified. In each district all the cases were removed to hospital, and there were no deaths. In Adwick, 20 of the 30 cases occurred in unvaccinated persons; in Bentley, 62 of the 77 were unvaccinated. In each report Dr. Dunne points out the vital importance to the health and well-being of the community of a pure atmosphere and laments that nothing is being done to prevent the beauty of the countryside being ruined by the blight from the chimney stacks, and that what is bad for vegetation is also bad for human beings. In both these districts the population is growing rapidly, and Dr. Dunne considers the Registrar-General's population is an underestimate. In Adwick 401 houses were erected during the year, and in Bentley 120, of which latter number 46 were part of a municipal scheme.

Thedwastre and East Stow.

Dr. S. C. Hounsfield reports that the 18-bed isolation hospital which serves these two rural districts and Stowmarket urban district is quite out of date, that negotiations with the Ministry for the building of new wards have been completed, and that the work is to be put in hand at once. One of the most urgent needs of East Stow is the cleaning out of the river Gipping, the silted-up bed of which blocks the natural drainage of the district and creates serious flooding and sanitary difficulties. The proposal of the county council to provide work for the unemployed in cleaning out the river has unfortunately fallen through. Dr. Hounsfield says the housing problem is a pressing one in both districts. Overcrowding cannot be abated and unfit houses cannot be closed.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 24TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week—namely: small-pox, 101; scarlet fever, 1493; diphtheria, 759; enteric fever, 116; pneumonia, 869; puerperal fever, 40; cerebro-spinal fever, 7; acute poliomyelitis, 7; encephalitis lethargica, 261; dysentery, 8; ophthalmia neonatorum, 167. There were no cases of cholera, plague, or typhus fever notified during the week. Of the cases of small-pox, 4 were notified from Cumberland (Workington 2, Cockermouth R.D. 2), a new locality; from the county of Derby 42 (23 of these from Chesterfield), from Northumberland 19 (all from Ashington), from Yorks, N. Riding 16 (all from Middlesbrough).

Deaths.—In the aggregate of great towns the deaths from influenza fell further from 73 to 67. There were in London 9 deaths from diphtheria, 17 only from measles. One death from small-pox was registered in Middlesbrough.

Obituary.

FORBES FRASER, C.B.E., F.R.C.S. ENG.

THE death of Mr. Forbes Fraser at Bath on May 28th, as the late result of an operating wound, removes a surgeon in the prime of life with a record distinguished alike at home and on the field of battle.

Forbes Fraser was born in 1871, the younger son of Mr. Henry Fraser, of Arbroath. At the age of 16 he entered St. Bartholomew's Hospital with an entrance scholarship, and his hospital career was a chapter of successes. He won the Harvey prize, the Brackenbury surgical scholarship, and the gold medal in physiology at the Intermediate London M.B., taking the Conjoint Diploma in 1894 and the F.R.C.S. Eng. in 1896, when he passed the examination a year before reaching the age when the diploma could be conferred. On leaving the hospital, where he became Mr. Butlin's house surgeon, Fraser engaged for three years in practice at Tarporley in Cheshire, where by dint of rising early and working late he found time to hunt and win prizes in point-to-point races. In 1900 he settled in Bath as the partner of Mr. Pagan Lowe. His long connexion with the Royal United Hospital began in 1903, when he was appointed assistant surgeon; at the time of his death he was senior surgeon. He was also consulting surgeon to the Ministry of Pensions Hospital, Bath, and to the hospitals at Chippenham, Frome, Malmesbury, and Shepton Mallet.

FORBES FRASER.

During the war Fraser joined the Duchess of Westminster's Hospital as surgeon and spent many active months at Le Touquet; it was then that beneath his guise of mildness there became revealed an inflexible doggedness in the pursuit of such things as he felt to be important. His colleagues there found him a fine and original surgeon, who might have becone a dominating figure in this field had he earlier become consulting surgeon to an army. In 1917 he took up special work at No. 10 Casualty

Clearing Station, Remy Siding, the results of which were published in the *British Journal of Surgery* under the title Primary and Delayed Primary Suture of Gunshot Wounds Subsequently most of his work was at one or other C.C.S. The advent of his surgical team was always welcome where active fighting was in progress. It is related of Fraser that the strain of battle-surgery never ruffled him, and in a tired, overworked operating theatre he radiated energy, good temper, and contentment. These qualities, combined with a sound knowledge of surgery and rare judgment, led to his appointment as consulting surgeon to the Second Army, and when after the armistice this army entered Germany he became consulting surgeon to the Army of the Rhine. He retired from the Army with the rank of Colonel A.M.S. and the C.B.E.

Fraser's return to Bath found him fresh outlets for his energy. The necessity of coördinating the medical services of the civil community was borne in upon him; and being singularly receptive he aimed at linking up well-equipped cottage hospitals and hospitals in smaller towns with the Royal United Hospital, Bath. Lack of funds, unfortunately, made it impossible to embark on the complete scheme. A beginning, however, was made, and we recorded only a week or two ago the opening of the Royal United Private Hospital and of the Orthopædic Hospital at Combe Park. The first patient was admitted to the latter on the day of Fraser's death; perhaps, said one of his friends, he would have wished no more fitting commemoration.

In his own circle Fraser worked unremittingly for harmony and good fellowship. He was an active member and founder of various surgical clubs, among them the Country Surgeons Club, the Bath and Bristol Surgical Club; he had been president of the Bath Clinical Society, and was a member of the committee of the Bristol Medico-Chirurgical Society. For the last two years he had arranged courses of post-graduate instruction at the Royal United Hospital, which were well attended. His Bath colleagues recently proved their high appreciation of his worth in recommending him as president-elect for the annual meeting of the British Medical Association to be held in 1925 at Bath.

In appearance Forbes Fraser was a Nordic, tall and spare, with clear blue eyes and ruddy complexion. His manner was unassuming, so that his modesty sometimes passed for diffidence, but behind this lay great self-reliance and unswerving determination to get the best out of himself and everyone round him. The high reputation of Bath as a city of healing owes not a little to his powers of organisation and straightforward dealing. His favourite recreation was salmon-fishing, and much of his spare time was spent fishing the trout streams of Wiltshire. He was also a keen motorist. He was a man whose friendship was highly prized.

His fellow practitioners at Bath write: "He was a staunch colleague and a loyal, kindly, and generous friend. Of a highly sensitive and somewhat emotional nature, he always kept himself firmly in hand and rarely allowed his feelings to overcome his habitual suavity of manner and speech. Conspicuously honourable and straightforward in all he did, he had the most bitter contempt, which he never hesitated to express, for anything suggestive of cant, humbug, or meanness of purpose. His enthusiasm, energy, and strong sense of public duty were an inspiration to all, and the affectionate regard in which he was held by all classes of the community is no more than a fitting tribute to one whose whole life was characterised by integrity of purpose, brilliancy of achievement, and unfailing kindness in all he did."

Forbes Fraser was twice married. By the first marriage he leaves two sons and three daughters, his eldest son being a medical student at St. Bartholomew's Hospital. By the second marriage there is one daughter. His second wife survives him, and to her and all his family we extend our sympathy.

DR. BRUNO BANDELIER.

NEWS has only just reached us of the death at Schömberg, near Wildbad, of Dr. Bandelier, who was latterly medical director of the Schwarzwaldheim Sanatorium after having held the position of senior physician of Dr. Weickers's institute at Görbersdorf and director of the sanatorium at Cottbus. He was one of the principal advocates in Germany of tuberculin treatment in rapidly repeated and increasing doses, with the aim of reaching a high degree of tuberculin tolerance, and in conjunction with Dr. O. Roepke, of Stadtwald, near Cassel, brought out, many years ago, the "Handbuch der Diagnose und Therapie der Tuberkulose," which has gone through seven German editions and has been twice translated into English under the title "Tuberculin in Diagnosis and Treatment." Dr. Bandelier also collaborated with the same author in the "Klinik der Tuberkulose," which dealt with the application of treatment in all the various localisations of the tubercle bacillus. Bandelier's methods were logical and safe, and in his own practice he eliminated to a vanishing point the risks attendant on tuberculin administration. His industry was almost incredible in summarising and abstracting—which he did with conspicuous fairness—the colossal accumulation of literature on tuberculin. Few, if any, therapeutic means have ever been laid before the medical profession with the principles so carefully worked out and the pitfalls so carefully noted. Whatever place tuberculin may finally take in the practitioner's outfit, the faithful work of Bandelier will remain.

Medical News.

UNIVERSITY OF LONDON: *University College.*—A public lecture on Some Recent Experimental and Statistical Studies on the Alcohol Problem, will be delivered by Prof. Raymond Pearl, of the Dept. of Biometry and Vital Statistics, Johns Hopkins University, U.S.A., on June 24th, at 5.30 P.M. The lecture is open to the public without fee or ticket, and will be held in the theatre of the Department of Applied Statistics and Eugenics of University College, Gower-street, W.C.

At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—Kathleen D. Arnsby (*b*), London Sch. of Med. for Women; Edward Gallop (*a*, *e*), St. Bart.'s Hosp.; Dorothy Gibson (*a*, *d*, University Medal), London Hosp.; William O. C. Jarratt (*d*), St. Thomas's Hosp.; James Maxwell (*a*, *e*), St. Bart.'s Hosp.; Alfred T. Rogers (*d*), Guy's Hosp.; Wilfrid P. H. Sheldon (*a*), King's Coll. Hosp.; Hilda N. Stoessiger (*b*), London Sch. of Med. for Women; Thomas C. Summers (*d*), London Hosp.; and Harold F. Walker (*e*), Middlesex Hosp.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Isaac Atkin, St. Bart.'s Hosp.; Rose Baranov, Univ. Coll. Hosp.; Lancelot G. Bourdillon, St. Thomas's Hosp.; Doris K. Brown, London Sch. of Med. for Women; James W. Brown, Middlesex Hosp.; Dorothy E. B. Buckmaster, London Hosp.; Harold Burt-White, St. Bart.'s Hosp.; Grace D. Chambers, St. Mary's Hosp.; Charles E. Cobb, St. Thomas's Hosp.; Doris B. Collier, Univ. Coll. Hosp.; Elizabeth M. Cowie and Hilda M. Cunnington, London Sch. of Med. for Women; John A. Currie, Guy's Hosp.; Donald Davidson, King's Coll. Hosp.; Mahmoud Abu Bakr Demerdash, Univ. Coll. Hosp.; Henry T. Edmunds, King's Coll. Hosp.; Barbara J. Edwards, University of Birmingham; Lucy M. Elsom, King's Coll. Hosp.; Wilfred M. Evans and Richard F. Fagan, Univ. Coll. Hosp.; Louis Forman, Guy's Hosp.; Charles A. H. Franklin and Leslie French, St. Thomas's Hosp.; George F. Gibberd, Guy's Hosp.; Laura P. Gibbon, London Hosp.; Rachel Halperin, Univ. Coll. Hosp.; James R. Hamerton, St. Bart.'s Hosp.; Greta Hartley, London Sch. of Med. for Women; Linley I. Henzell, Univ. Coll. Hosp.; Aglionby D. Hepburn, Westminster Hosp.; Gwynedd Hugh-Jones, and Kathleen M. Hyslop, London Sch. of Med. for Women; John T. Ingram, London Hosp.; Reginald Keene, St. Bart.'s Hosp.; Lorna S. King, St. Mary's Hosp.; Robert A. E. Klaber, St. Bart.'s Hosp.; Ardeshir Jahangirshah Kohiyar, Univ. Coll. Hosp. and Grant Medical College; Gladys M. Lambourne, St. Mary's Hosp.; Ronald E. Lane, and Jehiel J. Lewinstein, Guy's Hosp.; Francis Louis, Univ. Coll. Hosp.; Eveleen Lyles, London Sch. of

Med. for Women ; Lucy M. T. Masterman, London Sch. of Med. for Women and St. Mary's Hosp. ; George O. Mitchell, Guy's Hosp. ; Clifford I. N. Morgan, St. Bart.'s Hosp. ; Richard M. Morris, London Hosp. ; Una F. M. Morton, Univ. Coll. Hosp. ; Louis Mushin, London Hosp. ; Grace H. Newell, Frances L. Nichol, and Lucy Parker, London Sch. of Med. for Women ; Alan C. T. Perkins, King's Coll. Hosp. ; Ethel A. Perrott, London Sch. of Med. for Women ; John W. G. Phillips, London Hosp. ; Jeffrey W. Poole, St. Bart.'s Hosp. ; Kenneth N. Purkis, Guy's Hosp. ; Margaret E. Reynolds, London Sch. of Med. for Women ; Stanley H. Robinson, Guy's Hosp. ; May K. Ruddy, Charing Cross Hosp. ; Frank P. Schofield, St. Bart.'s Hosp. ; Harold B. Shaw, Middlesex Hosp. ; Patricia H. S. Shaw, St. Mary's Hosp. ; Abraham I. Silverman, Middlesex Hosp. ; Harvie K. Snell, King's Coll. Hosp. ; Doris M. Stone and Margaret Swete, London Sch. of Med. for Women ; Arthur W. Taylor, St. Bart.'s Hosp. ; William Thomas, London Hosp. ; John H. Thompson, Univ. Coll. Hosp. ; Percy Thwaites, St. Bart.'s Hosp. ; Maurice A. Townshend and Eileen M. Turner, Univ. Coll. Hosp. ; Hermione M. Usborne and Dorothy M. Vaux, London Sch. of Med. for Women ; James A. Walker, St. Mary's Hosp. ; Robert G. R. West, St. Bart.'s Hosp. ; Joan F. Whitelock, Univ. Coll. Hosp. ; Emrys Williams, St. Thomas's Hosp. ; John G. Wilson, Westminster Hosp. ; and Esther Wingate and Isabelle J. Woodhouse, London Sch. of Med. for Women.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—H. C. Clifford-Smith, Charing Cross Hosp. ; J. H. Cooper, Glasgow ; W. R. A. Line, Birmingham ; R. Schofield, Guy's Hosp. ; and L. Statnigrosch, Middlesex Hosp.

Medicine.—E. J. Creais, St. Mary's Hosp. ; W. R. A. Line, Birmingham ; E. J. P. McDowell, St. Thomas's Hosp. ; J. P. McGuire, St. Mary's Hosp. ; and W. T. Swanton, Cork and Charing Cross Hosp.

Forensic Medicine.—F. H. Armanious, St. Thomas's Hosp. ; R. Hare, St. Mary's Hosp. ; W. R. A. Line, Birmingham ; and E. J. P. McDowell, St. Thomas's Hosp.

Midwifery.—K. R. Chaudhri, St. Mary's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : F. H. Armanious, J. H. Cooper, E. J. Creais, and L. Statnigrosch.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates, having passed the requisite examinations, have been admitted Diplomates in Public Health :—

Marion B. Armstrong, Dugald Baird, George Brewster, George Buchanan, Alexander A. Charteris, Alisdair C. Dewar, David R. Hamilton, Agnes M. Hill, Kenneth D. Mackintosh, Evelyn M'Pherson, Gilbert Paterson, Bessie S. Ross, Eva M. Sturrock, Joseph G. Tait, Sarah B. H. Walker, Marion Watson, Robert H. Williamson, and Jessie M. L. Wright.

London School of Hygiene and Tropical Medicine.—The court of governors, established under the Royal Charter incorporating the London School of Hygiene and Tropical Medicine, has now been constituted as follows : Sir Harry Goschen, Sir George Newman, and Sir W. Arthur Robinson, appointed by the Minister of Health ; Prof. H. R. Kenwood, Sir William J. R. Simpson, and Mr. H. J. Waring, by the Senate of the University of London ; Sir Arthur Clarke and Sir Ion Hamilton Benn, by the Seamen's Hospital Society ; Sir Gilbert Barling, Sir E. Coey Bigger, Dr. W. L. H. Duckworth, Prof. J. B. Leathes, Dr. John C. McVail, and Sir Humphry Rolleston, by the General Medical Council ; Sir Malcolm Delevingne, by the Home Secretary ; Sir Herbert Read, by the Colonial Secretary ; Colonel H. P. W. Barrow, by the Secretary of State for War ; Major-General Sir Richard Havelock Charles, by the Secretary of State for India ; Air Commodore D. Munro, by the Secretary of State for Air ; Surgeon Vice-Admiral Joseph Chambers, by the Board of Admiralty ; Mr. W. R. Buchanan Riddell, by the President of the Board of Education ; Sir A. Daniel Hall, F.R.S., by the Minister of Agriculture and Fisheries ; Sir W. Leslie Mackenzie, by the Secretary for Scotland ; Sir Frederick Andrews, F.R.S., by the Medical Research Council ; Sir Walter Fletcher, F.R.S., by the Royal Society ; Sir George S. Buchanan, by the Health Committee of the League of Nations ; Mr. W. Ray, by the London County Council ; Mr. Walter Eickhoff, by the Metropolitan Asylums Board ; Sir William Hodgson, by the County Councils Association ; Alderman Francis Askew, by the Municipal Corporations Association ; Sir David Bruce, F.R.S., by the Lister Institute ; Sir Henry Tanner, by the Royal Sanitary Institute ; Sir William R. Smith, by the Royal Institute of Public Health ; and Dr. R. A. Bolam, by the British Medical Association. The first meeting of the court was held at the Ministry of Health on May 29th, when 32 members were present. Mr. H. J. Waring was elected chairman of the court. The board of management has now been completed and is constituted as follows : Sir Alfred Mond, Sir George Newman, Sir Walter Fletcher, F.R.S., Sir E. Cooper Perry, Mr. H. J. Waring, Sir Arthur Clarke, Sir Humphry Rolleston, Colonel H. P. Barrow, and Dr. John Robertson.

Royal Society of Medicine.—A conversazione will be held in the Society's house, 1, Wimpole-street, W.1, on June 24th, at 9 P.M., when the President, Sir William Hale-White, will give a short address on the Story of "Say Ninety-Nine."

London (R.F.H.) School of Medicine for Women.—A post-graduate course of instruction for medical women in treatment of venereal diseases has been arranged jointly by this school, the Royal Free Hospital, the London Lock Hospital, and the Elizabeth Garrett Anderson Hospital. The course will begin on June 16th at 10 A.M., and will continue for two weeks. The number of persons admitted to the course will be limited to 12, and applications will be dealt with in the order received. The course is designed to be strictly practical in character, and a certificate will be issued to practitioners attending the full course to the satisfaction of their teachers. Those taking part include Mr. Johnston Abraham, Dr. Margaret Rorke, Lady Barrett, Colonel L. W. Harrison, Mr. Charles Gibbs, Dr. Ruth Balmer, Mr. J. E. R. McDonagh, Mr. Laurence Abel, Major W. Victor Corbett, and Mr. Lindsay Rea. Application should be made to the Warden and Secretary at the School, 8, Hunter-street, W.C.

Conference of the International Union against Tuberculosis.—The fourth conference will be held at Lausanne, Switzerland, on August 5th, 6th, and 7th, and a provisional programme has now been issued. The subject for the first discussion, to be held at 2 P.M. on August 5th, will be opened by Prof. A. Calmette, and will deal with the following problem : Do there exist in nature or can there be artificially produced saprophytic varieties of Koch's bacillus which possess the property of becoming virulent tubercle bacilli ? At 5 P.M. Prof. H. Sahli will lecture on the Defence of the Organism against the Tubercle Bacillus. On August 6th, at 10.30 A.M., a discussion on the Relationship Between Pregnancy and Tuberculosis will be opened by Prof. J. H. Forssner ; and at 5 P.M. Prof. Léon Bernard will lecture on Prophylaxis in Childhood against Tuberculosis. On August 7th, at 9.30 A.M., a discussion on the Effects of the Anti-Tuberculosis Campaign on the Diminution of the Mortality from Tuberculosis in Different Countries will be opened by Sir Robert Philip. A visit to the principal anti-tuberculosis centres in Switzerland will be arranged, to start on August 8th. The itinerary will include : Leysin, Montana, Heiligenschwendi, Berne, Zurich, Davos, and Arosa. The tour will take about eight days. Application for admission as an ordinary member of the union (annual subscription £1) should be made not later than June 16th to Miss Freda Stickland, secretary, National Association for the Prevention of Tuberculosis, 20, Hanover-square, London, W. 1, from whom further particulars can be obtained.

Livingstone College.—Commemoration day at Livingstone College was held on May 31st, when a large number were present. The chair was taken by Sir William J. R. Simpson. The Principal of the College said that 36 students had entered the College during the present session. He spoke of the encouraging reports received from former students of the value of the training received at the College, and emphasised the need for an increase of students and subscriptions to carry on the work more usefully in the future. A cheque, amounting to £52 17*s.* 9*d.*, was handed to the treasurer, Mr. R. L. Barclay, by the senior student, on behalf of the past and present students, to help meet the cash deficit, as a token of gratitude, esteem, and good will. The treasurer said that the financial side of the work of Livingstone College for the last few years had been one of considerable anxiety. He referred to the fact that the College had to depend on the fees of students and the subscriptions of a few friends for its upkeep. It was necessary to increase the number of students, and until that is an accomplished fact further subscriptions are called for. About £500 are needed to balance the cash account before Sept. 30th. The chairman said that the course at Livingstone College is an excellent one, and one that will be most useful to the missionary in order to teach him how to care for his own health, and to get into the hearts of the people amongst whom he works. The students of this College were taught the methods of prevention of malaria, dysentery, and cholera, and in this way are most helpful to the sanitary authorities.

Messrs. William Heinemann (Medical Books), Ltd., announce the forthcoming appearance of a book on Encephalitis Lethargica by Prof. Aug. Wimmer, containing a preface by Sir Frederick Mott.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of this society will take place at the Trocadero Restaurant, Piccadilly, London, W., on June 13th. Sir W. H. Willcox, the President, will take the chair.

The Cavendish Lecture will this year be delivered by Sir Robert Jones on Some Points in Manipulative Surgery, at the Kensington Town Hall, London, W., at 8.15 P.M., on June 20th. A conversazione will follow, at which many firms will provide medical and surgical exhibits.

GLASGOW UNIVERSITY CLUB, LONDON.—The annual summer dinner will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 27th, at 7.30 P.M., Lieut.-Colonel John Buchan in the chair. Any Glasgow University men, not members of the Club, who desire to attend the dinner are requested to communicate with the hon. secretaries, 1, Harley-place, N.W. 1.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The prize founded by Dr. J. T. Neech for the best paper read in each session before a branch or group of the Society of Medical Officers of Health has been awarded to Dr. C. O. Stallybrass for his paper entitled Encephalitis Lethargica; Some Observations on the Recent Outbreak, read before the North-Western branch in May, 1922. The assessors for the prize were the President (Dr. T. W. Naylor Barlow), Prof. H. R. Kenwood, Dr. W. J. Howarth, and Dr. R. A. Lyster.

WESTMINSTER CIVIC DINNER.—On Monday, June 2nd the Public Libraries, Public Baths and Watch Committees of the City of Westminster were entertained at a dinner held in the Savoy Hotel, at which the Mayor of Westminster, Councillor Edgar Horne, J.P., occupied the chair. The toast of "The Libraries, the Baths, and Watch Committees" was proposed by the chairman, who referred to the excellent and enterprising work which had been carried out by these three sections. The toast was responded to by Councillors the Rev. Jocelyn Perkins, Major W. C. Hussey, and George H. Heilbuth, respectively, for each committee. "The Visitors" were toasted by Alderman Sir Robert Walden, and there replied Mr. H. A. L. Fisher and Mr. A. R. Dyer, chief officer of the London Fire Brigade. Sir Edward Thesiger gave the "City of Westminster" and the Mayor replied. A pleasant musical programme was contributed by the Westminster Singers. Among others present were: Brigadier-General R. H. More, Sir Robert Sanders, Colonel Arthur Brodrick, Sir John Horsburgh-Porter, Mr. F. L. D. Elliot (Assistant Commissioner of Police), Mr. C. K. Francis, The Very Rev. Father Russell, Sir Henry New, Mr. Sidney C. Harper (the Mayor of Islington), and Lieut.-Colonel H. M. Pryce-Jones.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Commencing on Monday, June 16th, the Royal Northern Hospital will give, in conjunction with the Royal Chest Hospital, a two weeks' intensive course, including all the general and special departments of medicine and surgery. The Wednesday sessions will be undertaken by the Royal Chest Hospital, but apart from these the work will be carried out at the Royal Northern Hospital, and includes demonstrations of clinical methods and cases in the mornings and afternoons, followed by a formal lecture, open to members of the profession, at 4.30 P.M. At St. Peter's Hospital there will be a four weeks' special course in urology from June 16th to July 12th, which will consist of clinical work daily, in addition to formal lectures on the various aspects of urinary diseases. Beginning also on June 16th the Children's Clinic (Western General Dispensary) has arranged a series of nine lecture-demonstrations on children's diseases. The last demonstration and lecture will take place on Friday, July 4th, and will be given by Dr. Bernard Myers at the Royal Waterloo Hospital. Courses already in progress are Gynæcology at the Chelsea Hospital for Women, Diseases of Tropical Countries at the London School of Tropical Medicine, both of which will conclude on the 27th of the month. The following courses have been arranged for July and August: Cardiology, at the National Hospital for Diseases of the Heart; General Intensive Course, at the North-East London Post-Graduate College (Prince of Wales's General Hospital); Diseases of the Chest, at the Brompton Hospital; and Neurology, at the West-End Hospital for Nervous Diseases. Copies of the syllabus and full particulars of any of the above courses can be obtained from the secretary to the Fellowship of Medicine, at 1, Wimpole-street, London, W. 1.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, MAY 28TH.

Therapeutic Substances Bill.

THE Therapeutic Substances Bill was read a third time.

THURSDAY, MAY 29TH.

Cost of Medical Benefit.

The National Health Insurance (Cost of Medical Benefit) Bill received the Royal Assent by Commission.

HOUSE OF COMMONS.

TUESDAY, MAY 27TH.

International Restrictions on Use of Lead Paint.

Mr. D. G. SOMERVILLE asked the Home Secretary the numbers and names of those Powers signatory to the International Labour Organisation Convention of Nov. 19th, 1921, who had either ratified the proposed restrictions on the use of lead paint or had laid legislation to that end before their respective legislatures; and whether he would give the names and numbers of those Powers concerned who had taken no such action.—Mr. HENDERSON replied: I have consulted with my right hon. friend, the Minister of Labour, on this matter. Our information is that three Powers—namely, Czecho-Slovakia, Esthonia, and Sweden—have formally ratified the Convention, though I understand that in the case of Czecho-Slovakia legislation to give effect to the provisions of the Convention has not yet been passed. Ratification has been authorised, though not formally registered, in the case of four other Powers—Austria, Greece, Italy, and Poland. In the case of seven countries—Bulgaria, Chili, Cuba, Germany, Latvia, Netherlands, and Spain—legislative proposals to give effect to the draft Convention have been laid before the respective legislatures. Draft Conventions adopted by the International Labour Conference are not signed. Of the 54 members of the International Labour Organisation at the time of the third session of the Conference in 1921, 39 were represented at the Conference; in the case of Albania, Bolivia, Canada, China, Finland, Guatemala, India, Japan, Roumania, Siam, and Venezuela the Government representatives did not vote for the draft Convention. So far as I am aware, the remaining countries represented at the Conference—namely, South Africa, Australia, Belgium, Brazil, Columbia, Denmark, France, Luxembourg, Norway, Portugal, Kingdom of the Serbs, Croats and Slovenes, Switzerland, and Uruguay—have, as yet, not brought before their respective legislatures legislation designed to give effect to the draft Convention. I would add that in France the use of white lead in painting operations carried out by operative painters, whether on the exterior or interior of buildings, is prohibited by a decree dated July 20th, 1909.

Encephalitis Lethargica.

Sir PHILIP DAWSON asked the Minister of Health the number of cases of encephalitis lethargica reported during the 12 months ended May 30th, 1924; the number reported during the corresponding period of the preceding year; and the total number of deaths in the periods mentioned.—Mr. WHEATLEY replied: The figures for the actual periods mentioned in the question are not available, but the following table gives the particulars required for each quarter in 1922 and 1923, and for the first 20 weeks of the present year:—

Notifications.		*Deaths.*	
13 weeks ended—	England and Wales.	Quarter ended—	England and Wales.
Apl. 1st, 1922	140	Mar. 31st, 1922	95
July 1st, ,,	132	June 30th, ,,	96
Sept. 30th, ,,	89	Sept. 30th, ,,	82
Dec. 30th, ,,	93	Dec. 31st, ,,	66
Mar. 31st, 1923	448	Mar. 31st, 1923	188
June 30th, ,,	279	June 30th, ,,	167
Sept. 29th, ,,	144	Sept. 30th, ,,	90
Dec. 29th, ,,	154	Dec. 31st, ,,	86
Mar. 29th, 1924	753	Mar. 31st, 1924	229‡
May 17th,* ,,	1715†	May 17th,* ,,	?

* Seven weeks ended. † Uncorrected. ‡ Approximate.

The notifications in England and Wales during the 52 weeks ended June 2nd, 1923, were 868, and during the 50 weeks ended May 17th, 1924, were 2829. (Uncorrected figures for last seven weeks as above.)

WEDNESDAY, MAY 28TH.

Maternity Convention.

Mr. WHITELEY asked the Minister of Labour whether it was the intention of the Government to bring the Maternity Convention decisions before the House for ratification during the present session; and, if not, whether he could give any assurance that they would be dealt with during the autumn session.—Mr. T. **SHAW** replied: I am still in consultation with my right hon. friend, the Minister of Health, regarding the policy to be adopted by His Majesty's Government in connexion with this draft Convention. I cannot at present make any further statement.

Royal Commission on Lunacy Laws.

Major **MOULTON** asked the Minister of Health whether he was now prepared to form the proposed committee to inquire into the lunacy laws: and whether, pending its report, he would take steps to provide for more frequent inquiries into the mental state of patients detained in asylums by persons extraneous to such asylums.—Mr. **WHEATLEY** replied: I hope that a Royal Commission will be appointed within the next few weeks. Pending their report, I will continue to keep a careful watch on the administration of the Lunacy Acts.

Public Health Services Inquiry.

Mr. **MONTAGUE** asked the Minister of Health whether he was prepared to appoint a court of inquiry to investigate and report upon the prevailing conditions of the public health service of the country.—Mr. **WHEATLEY** replied: I do not, as at present advised, see any necessity for such a general inquiry as is suggested, since there is clearly room for further expansion and improvement of the services on what is already known about them.

Compulsory Segregation of Tuberculosis Cases.

Mr. **BLACK** asked the Minister of Health whether he would state the policy of the Government with respect to the compulsory segregation of persons seriously affected with tuberculosis and in an infectious and incurable condition; and whether he could promise adequate protection to the children and near relatives of such persons who were, through lack of housing accommodation, forced to live in close proximity to such diseased persons.—Mr. **WHEATLEY** replied: As regards the first part of the question, this matter will be considered in connexion with any proposals for the amendment of the Public Health Acts. As regards the second part, it is for the local sanitary authorities to take all such steps as are practicable to prevent the spread of infection.

Cost of a Poor-law Institute.

Mr. **LINFIELD** asked the Minister of Health the average cost, including food, clothing, medicine, attendance, doctors' fees, and all overhead charges, of a Poor-law institute.—Mr. **WHEATLEY** replied: In the financial year 1922–23 the average weekly cost per inmate of all the Poor-law institutions in England and Wales was about 26*s.* 6*d.* This amount includes food, clothing, medicine, fuel, and lighting; salaries and other remuneration of doctors, masters, matrons, nurses, attendants, and other persons; the cost of the upkeep of buildings and furniture; rent, rates, taxes and insurance, interest on loans for capital works and provision for repayment of such loans.

Smoke Abatement.

Mr. **LORIMER** asked the Minister of Health if he was aware that public opinion was ready and eager to strengthen the Public Health Act of 1875 regarding smoke abatement; that many of the largest towns in the country had given up attempts to prevent atmospheric pollution under the Public Health Act, and had applied to Parliament for special powers; and was he ready to grant the special powers asked for.—Mr. **WHEATLEY** replied: The Government hope to introduce a Bill dealing with this subject at an early date.

National Health Insurance.

Mr. **WILLIAM M. ADAMSON** asked the Minister of Health whether the National Health Insurance (Prolongation of Insurance) Act was to be renewed for the year 1925.—Mr. **WHEATLEY** replied: The question of the extension until Dec. 31st, 1925, of the National Health Insurance (Prolongation of Insurance) Act is receiving consideration; but I am not yet in a position to make a definite announcement on the subject.

THURSDAY, MAY 29TH.

Revision of Pension Awards.

In reply to Mr. **LANSBURY**, Mr. F. O. **ROBERTS**, Minister of Pensions, said: I am aware that among the cases of disabled ex-Service men and dependents of men who lost their lives in the late war, there are some which on merits call for reconsideration. I am glad to be able to inform my hon. friend that, by an extension of arrangements initiated by my predecessors, I have now been enabled to secure that all cases in which additional evidence is furnished shall be fully considered and a suitable grant made, with the assistance of the Treasury, if the disability or death is now found, in the light of all the evidence available, to be due to service in the late war. The necessary arrangements are being made to enable such cases, if they are referred to local or regional offices, to be dealt with.

Meals for Necessitous School-children.

Mr. **NIXON** asked the President of the Board of Education how many necessitous children received meals in elementary schools; how many meals were served in 1923; and what was the cost per meal.—Mr. C. **TREVELYAN** replied: The latest period for which I have complete figures is the year ending March 31st, 1923. During that year 149,676 children received school meals under the provisions of the Education Act, 1921; of these, 127,636 received free meals. The total number of meals provided was 17,171,298, of which 14,991,798 were provided free. The average total cost per meal was 3·6*d*. During the calendar year 1923, 11,463,487 meals were provided, of which 9,357,557 were provided free.

MONDAY, JUNE 2ND.

Army Hospitals in India.

Mr. **BROAD** asked the Under Secretary of State for India: (1) How far effect had been given to the recommendations of Lord Inchcape's Committee on Retrenchment to reduce the number of Army hospitals and the number of beds in those which were retained; and whether any and, if so, what reduction had been made in the hospital staffs as recommended by that committee; and (2) whether, seeing that the Inchcape Retrenchment Committee reported that British hospitals in India were not used to a quarter of their capacity and Indian hospitals only to a third of their capacity, and that they made recommendations for the reduction of the number of hospitals, beds, and staffs, whether any action was taken on these recommendations; and what was the financial saving in consequence.—Mr. **RICHARDS** replied: The following action has been taken on proposals of the Indian Retrenchment Committee regarding medical services and hospitals. The number of beds in the British and Indian station hospitals has been reduced by the amounts shown below:—

	British station hospitals.	Indian station hospitals.
Northern command	1016	1180
Southern ,,	466	582
Eastern ,,	331	184
Western ,,	83	95
Burma district	61	—

A reduction of 15 officers of the Indian Medical Service has been carried out and the services of 60 assistant surgeons are being dispensed with. A saving of Rs.5 lakhs was anticipated from these reductions, but the actual net saving is not yet known.

Civil Surgeons in United Provinces.

Mr. **HOPE SIMPSON** asked the Under Secretary of State for India how many civil surgeons are employed in the United Provinces, and of these how many were commissioned European officers.—Mr. **RICHARDS** replied: There are 50 civil surgeons in the United Provinces. On Jan. 1st last these included 15 European officers of the Indian Medical Service and 10 officers of the Indian Medical Department.

Royal Commission on Lunacy Laws.

Mr. **COSTELLO** asked the Prime Minister whether, in view of the fact that the provisions of the Scotch Lunacy Acts differed in many particulars from those of the English Lunacy Acts, it was intended to include in the terms of reference to the Royal Commission on Lunacy about to be appointed the question of Scotch administration in addition to English administration of these Acts; and, since the administration of a Government department might be called in question in the course of the inquiry, would he consider the question whether it was undesirable to appoint to the Commission any person holding office under the Government.—Mr. **MACDONALD** replied: It is not intended to include in the terms of reference of the proposed Royal Commission the question of lunacy law and administration in Scotland. With regard to the second part of the question, I do not think it undesirable to appoint a member of the Government to be a member of the Commission if his personal qualifications are such that the appointment would strengthen the Commission.

TUESDAY, JUNE 3RD.

Vivisection of Dogs.

Lieut.-Commander **KENWORTHY** presented a Bill to prohibit the vivisection of dogs. The Bill was read a first time.

Cruelty to Children.

Dr. **SPERO** asked leave to introduce a Bill to amend the Children Act 1908 in respect of punishments for second or subsequent convictions by abolishing the option of a fine. The Bill, he said, would greatly reduce the number of cruelty cases in regard to children.

Mr. **FOOT** opposed the Bill on the ground that it was ill-conceived and would not achieve its purpose.

A division was challenged, but as only three members rose in support of this demand, the Speaker declared that leave to introduce the Bill was refused.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Thursday, June 12th.—5 P.M., Dr. M. G. Hannay: Lichenification.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street. W.C.

Thursday, June 12th.—4 P.M., Dr. Frew: Infant Feeding.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL,

Thursday, June 12th.—5 P.M., Mr. Richard Lake: Middle-Ear Disease. (Geoffrey E. Duveen Lectures in Otology.)

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

Monday, June 9th.—(At the Children's Hospital.) Dr. Fordyce: Medical Cases.

Tuesday.—(At the Southern Hospital.) Mr. Armour: Injuries of the Forearm, Wrist, and Hand.

Wednesday.—(At the Northern Hospital.) Dr. Pemberton: Jaundice.

Thursday.—(At the Stanley Hospital.) Dr. Wadsworth: Acidosis.

Friday.—(At the Royal Infirmary.) Dr. John Hay: Electrocardiograph Demonstration.

Appointments.

Critchley, Elizabeth E., M.B., Ch.B. Edin., has been appointed Resident Medical Officer, Fulwood Institution, Preston.

Litt, John Percy, M.D. Edin., Medical Officer of Health and School Medical Officer for the Borough of Lytham, St. Annes.

Lodge, W. Oliver, M.D. Leeds, F.R.C.S. Edin., Consulting Ophthalmologist to the Bradford Corporation.

Maguire, C. C. W., M.R.C.S., L.R.C.P. Lond., Medical Registrar, Queen's Hospital, Birmingham.

Rodgers, J. H., L.R.C.P., L.R.C.S. Edin., Medical Officer, Weymouth District Board of Guardians.

Willesden Urban District Council: Champneys, W. D., M.A., M.B., Ch.B., D.P.H., Assistant M.O.; and Gray, Alice J., M.A., M.B., Ch.B., D.P.H., Resident M.O.

Medical Referees under the Workmen's Compensation Act: Odell, R., M.D. Durh. (St. Albans, Barnet, Hertford, and Watford); May, Sir Gould, M.D. Camb. (West London); and MacFadden, C. J. R., M.D. Edin. (Marylebone). Cripps, F. R., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts (Patrington, York).

Vacancies.

For further information refer to the advertisement columns.

Alton, Hampshire, Lord Mayor Treloar Cripples' Hospital and College.—Jun. Asst. R.M.O. £250.

Ashton-under-Lyne District Infirmary.—H.S. £150.

Bahamas.—Bacteriologist and Asst. M.O.H. £600.

Barbados General Hospital.—Res. S. £330.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £160.

Bournemouth, Royal Victoria and West Hants Hospital.—Res. H.S. £150.

Breconshire, South Wales Sanatorium, near Talgarth.—Jun. Asst. R.M.O. £200.

Brighton, Hove Hospital, Sackville-road.—R.M.O. £175.

Bristol General Hospital.—Hon. Clin. Assts.

Bristol Royal Infirmary.—Hon. P. and Hon. Asst. P.

Canterbury, Kent and Canterbury Hospital.—Res. M.O. £175.

Cardiff, Welsh National School of Medicine.—Lecturer in Special Sense Physiology. £750.

City of London Maternity Hospital, City-road, E.C.—R.M.O. £100.

Derbyshire County Council.—Locum Tenens Tuberculosis Officer. £700.

Doncaster Royal Infirmary.—Jun. H.S. £150.

Dreadnought Hospital, Greenwich S.E.—H.S., and H.P. Each £150.

Dundee, King's Cross Infectious Diseases Hospital.—Sen. R.M.O. £350.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.P., H.S., Cas. M.O., and Cas. Surg. O. Each £100.

Harrogate Infirmary.—H.S. £150.

Hong-Kong Government.—Two M.O.'s. Also Asst. Port Health O. Each £600.

Huddersfield, Storthes Hall Asylum, Kirkburton.—Asst. M.O. £400.

Lambeth Parish Hospital.—Jun. Asst. M.O. £200.

Leeds University, Dept. of Pathology and Bacteriology.—Lecturer in Chemical Pathology. £600.

London Hospital, E.—First Asst. to each of the four Medical Firms. £400.

London Hospital Medical College.—University Chair of Medicine. £2000.

London Lock Hospital, 91, Dean-street, S.W.—Clin. Assts.

London Temperance Hospital, Hampstead-road, N.W.—R.M.O. £200.

Manchester Royal Eye Hospital.—Hon. Surg., Hon. Aural Surg., and Hon. Dental Surg.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. Path. £250. Also R.M.O. £200.

Newcastle-upon-Tyne, Princess Mary Maternity Hospital, Jubilee-road, City-road.—Asst. R.M.O. £40.

Nottingham General Hospital.—H.P., H.S., also H.S. for Ear, Nose, and Throat Dept. Each £150.

Queen Mary's Hospital for the East End, Stratford, E.—Hon. Asst. P., H.P., 2 H.S.'s, Obstet. H.S., also H.P. and Cas. O.

Royal Army Medical Corps.—20 Commissions.

Royal Northern Hospital, Holloway, N.—Anæsthetist. 10 guineas.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Non-Res. Cas. O. £150. Also Hon. P. to Outpatients.

Salford Royal Hospital.—Res. M.O. £175.

Sheffield Royal Infirmary.—Ophth. H.S., H.S., Asst. Cas. O., and H.S. to Ear, Nose, and Throat Dept. Each £60.

Stroud General Hospital.—H.S. £150.

University of London.—External Examiners.

West Bromwich and District Hospital.—Res. H.S. £220.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., Res. Cas. O. Each £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacancy at Lyndhurst, Hampshire.

Births, Marriages, and Deaths.

BIRTHS.

JAMES.—On May 25th, at Quatre Bras, Wellington College, Berks, the wife of Dr. Alfred H. James of a daughter.

TANDY.—On May 27th, at Avenue Elmers, Surbiton, the wife of Dr. Oswald Tandy of a daughter.

WILLIAMS.—On May 29th, at 30, Cumberland-terrace, Regent's Park, to E. Christine Pillman Williams, M.B.E., M.B., B.S., and E. Ulysses Williams, O.B.E., M.R.C.S., of 128, Harley-street—a son.

MARRIAGES.

STEWART—MOORE.—On May 5th, at St. Paul's Church, Durban, James Lennox Stewart, M.B., B.S. Lond., to Florence Evelyn Moore, daughter of Mr. and Mrs. C. T. E. Moore, of Leslie, Transvaal.

DEATHS.

BLACK.—On May 25th, at St. Mary's Hospital, Patrick Black, M.R.C.S., L.R.C.P., of asphyxia due to acute bronchopneumonia of both lungs, aged 43.

FRASER.—Forbes Fraser, C.B.E., F.R.C.S., of 5, The Circus, Bath, on May 28th, after five months' illness (pyæmia), aged 53.

WILKINSON.—On June 1st, at Osborne-villas, Windsor, Clement John Wilkinson, surgeon, in his 64th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

CINCHONA BARK: ITS ECONOMIC AND HYGIENIC RELATIONSHIPS.

IN the Chadwick lecture, delivered on June 4th at the Chelsea Physic Garden, Sir D. Prain discussed the Economic and Hygienic Relationships of Cinchona Bark and its Alkaloids. He said that European acquaintance with Peruvian bark had been traced to the cure in 1638 of a vicereine of Peru, who had contracted malaria, and whose name is perpetuated in that of the genus *Cinchona*. This bark became a forest product exploited in Loxa, now Southern Ecuador; it appeared first in a London pharmacopœia in 1677.

Exploitation of forest products may lead to narrowed supply, increased cost, and substitution. After 1753 the red bark of *C. succirubra*, from Chimborazo in Northern Ecuador, competed with the pale bark of *C. officinalis* from Loxa, which its exporters now termed crown bark. Europe thought red bark, although cheaper, as useful as crown; red became, and still remains, the only cinchona bark recognised as officinal. Trade substitution did not end here; the grey barks of *C. micrantha* and *C. nitida* from Huanuco in Central Peru competed with red, and their exploitation extended so as to include the yellow bark of *C. calisaya* from Bolivia. Scarcity of yellow bark led to the commercial exploitation of Colombian bark, obtained from *C. lancifolia*. As this was the last bark of importance to pharmacy that the rain forests of the Andes could supply, Europe undertook the cultivation of cinchona. Conversion of forest products into crops is subject to limiting factors. When labour is unprocurable, the crop must go where labour exists. France tried this crop in Algeria in 1849; Holland tried it in Java in 1851; England did so in Ceylon, the Nilgiris, and the Eastern Himalaya in 1861.

After labour comes environment. The soil and climate of Algeria did not suit cinchona; those of Java proved satisfactory. Ceylon and South India provided a suitable climate but a less satisfactory soil; in the Himalaya even the climate is marred owing to there being a distinct dry season.

Alkaloid Content of Barks.

After environment comes adaptability. Colombian bark is unwilling to thrive, even in Java. Red bark and grey prove accommodating, even in the Eastern Himalaya. Yellow bark can be planted in the Eastern Himalaya; it refuses to thrive in most parts of South India. There are limiting factors connected with utilisation as well as with production. Among the 40 cinchonas of the Andes, only six have proved of importance to pharmacy because of the alkaloid-content of their barks. Even in these important barks the alkaloid-content may vary naturally: 3 per cent. means a poor, 6 per cent. a good, 9 per cent. or over, a rich sample. Under cultivation, environment may induce further variation; barks "rich" in Java may be only "good" in South India or the Himalaya. This alkaloid-content factor has not inhibited the cultivation of any kind of cinchona; it has, however, rendered the careful selection of strains essential. The equally careful selection of kinds that, under existing conditions, is imperative, depends on the allied factor of alkaloid nature. The alkaloids of cinchona bark may be amorphous or crystallisable. All are remedial against malaria, the physiological action of the amorphous being more rapid than that of the crystallisable, and the efficacy of the crystallisable being accentuated when administered in an uncrystallised state. The chemical relationship of the amorphous to the crystallisable alkaloids is less clear than the inter-relationships of the crystallisable, whose remedial powers are believed to differ.

The crystallisable alkaloids in officinal cinchona bark were separated collectively for the first time in 1815. In 1820 this collective derivate yielded the specific alkaloid known as quinine; by 1852 it became known that, besides quinine, the "cinchonino" of 1815 includes other alkaloids—cinchonine, cinchonidine, and quinidine. The relative proportions of these alkaloids in particular kinds of cinchona remain unaffected by the variation in their percentages. In any sample of red bark one-half of the alkaloid-content is cinchonine, one-third quinine, one-sixteenth cinchonidine, only one-eightieth quinidine; the remainder—about one-eighth—is amorphous. But the relative proportions of these alkaloids differ in different kinds of cinchona bark. In red bark quinine forms but one-third of the alkaloid-content; in crown bark it forms three-fourths. In yellow bark the proportion of quinine is higher than in crown; in grey bark that proportion is lower than in red. When quinine was first isolated in 1820 yellow bark was the kind of most importance to pharmacy; quinine therefore became, and still remains, the only cinchona alkaloid that is officinal. Being the officinal alkaloid, quinine is the one chiefly prescribed and the one chiefly separated from cinchona bark in the factory. The manufacturer, when purchasing bark, pays for it in terms of its quinine-content; the planter, when establishing a plantation, stocks it with the kind of cinchona his environment will permit to thrive that is richest in quinine. It costs the manufacturer about as much to work up, and it costs the planter about as much to produce, a bark poor from the quinine standpoint, as it does to produce and work up a rich bark. The cinchona planter still grows some red bark because this is still required by pharmacy for officinal "bark preparations." But the quinine manufacturer no longer purchases red bark or grey, and the planter no longer raises any grey, nor will he grow crown if the environment and adaptability factors do not inhibit cultivation of yellow bark. Such, then, are the economic relationships of cinchona bark and its alkaloids.

These relationships are sometimes misunderstood. It has been said that bark production was abandoned in Ceylon because "cinchona, planted without scientific advice, began to deteriorate." It is believed that this has happened in South India owing to the establishment of a cinchona monopoly by Java. What happened in Ceylon was that, when coffee cultivation came to an end, cinchona cultivation was taken in hand. Ceylon, like South India, had to grow crown bark. When Ceylon began to harvest her cinchona the prices received were lower than the prices paid to Java for yellow bark. Ceylon, without hesitation, gave up cinchona and cultivated tea. The same economic factor has led to the abandonment of cinchona cultivation by private enterprise in South India.

The So-called Cinchona Monopoly.

What has been described as a cinchona monopoly in Java is no more than a *quinine* monopoly. That monopoly is not the creation of Java; it is a consequence of the fact that yellow bark, which does not thrive in South India, grows better in Java than in any area, outside Bolivia, where it has been tried. The preference of the planter everywhere for yellow bark is a result of the fact that the quinine-maker pays a better price for that bark. The action of the quinine-maker is itself a result of the accident that the hygienic relationships of quinine differ from those of the other alkaloids of cinchona bark. These hygienic relationships themselves appear at times to be misunderstood. Quinine may be the most valuable of the crystallisable alkaloids of cinchona bark; it certainly is not more valuable than the amorphous. Were this appreciated, we might be spared complaints as to the world-shortage of quinine. The manufacturer, who ought to know, seems to think these complaints exaggerated. Meanwhile the Java planter is less than content with the price he receives for his bark and explains that he cannot market all that he grows. This suggests over-production rather than shortage. Java, so far from establishing a monopoly, must have lost control of the bark market.

One consequence of this particular misunderstanding has been that our own dominions are unable to produce all the cinchona bark and its alkaloids that they require. To some this does not appear a serious matter; shortage of a remedy for malaria lends vigour to the crusade against its cause. We can appreciate this feeling: "prevention is better than cure." But others feel that, until malaria prevention has become more general, the provision of a recognised remedy remains a public duty. Medicine therefore urges the State to extend the cultivation of cinchona, within the Empire, wherever it can be grown. The appeal of medicine might carry greater weight if fuller account were taken of the effect on the economic relationships of cinchona of its hygienic relationships for which she is ultimately responsible. Medicine does not overlook these entirely; she regards all the alkaloids of one kind of cinchona as worthy of use, so long as they remain unseparated from the bark. It is only after the alkaloids have been separated from their bark that medicine feels constrained to regard all but one of them as unimportant. Even if it were true that quinine be a more effective remedy for malaria than its companions, it remains for consideration whether the treatment of these other alkaloids as waste products of no value be wholly justifiable. It is to this action on the part of medicine that the economic relationships which now exist owe their origin. If medicine can see her way to some modification of her present attitude, conditions that hamper State action and distress us all might disappear; full advantage could then be taken of cinchona bark and its alkaloids.

HEALTH CONFESSIONS OF BUSINESS WOMEN.

ON the principle that the wearer of the pinching shoe is best able to locate the pain, the Provincial Board of Health of Ontario has organised an inquiry among business women by business women into their mode of life. In the autumn of 1922 the Board's Division of Industrial Hygiene offered prizes for the best letters by business women on their health problems and solutions. The advertisement of this competition yielded between 200 and 300 letters, and these have been carefully edited and annotated so that excessive overlapping is avoided. The problems discussed are classified under such headings as The Psychology of Health, Board and Lodging, and Personal Maintenance. Thanks to the anonymity of pen-names, great frankness was encouraged, and it is evident from a perusal of this compilation[1] that the correspondents threw themselves heart and soul into the task of pooling their experiences for each other's benefit. The result is a book full of the hard-earned philosophy of office life, a human record of tears and smiles. In the matter of food alone there is a great wealth of wisdom tapped. The business woman has found that she must not satisfy a beefsteak appetite with warmed-up maccaroni, and that at 4 o'clock every day "you can see the 'cream-puffers' giving out—just about the time the 'midday diners' are waking up." It has also been found wise to board where men are boarding, to eat what men are eating—meat, vegetables and bread, not pastry and tea. One candid correspondent writes: "Cheap, badly cooked, greasy food and rich things affect my complexion right off, and I'd rather have a cheap hat than a 'cheap' skin, wouldn't you?" With regard to bodily cleanliness and habits, little faith is pinned on the sponge bath which *sounds* all right, but in practice is apt to dwindle and dwindle. "No girl can be self-respecting or respected if there is a 'low-water mark' anywhere on her." Another correspondent expresses the same thought in the brief sentence, "I always try to dress so I could be run over any day." Another urges her fellow-workers not to expect a gold locket or a string of pearls to be a sufficient covering for the chest. And so the stream of helpful, candid advice runs on, one little trick of the trade or labour-saving advice after another being thrown into the "pool." There are many shrewd hints on the psychology of life, and a wondrously wise correspondent writes that she cultivates the friendship of at least one girl who giggles and has the capacity for seeing humour in all things. Again and again this piece of advice appears: "Never yield to self-pity." Another maxim on the same line of thought is: "You may be more unlucky than many people, but you are more lucky than many others, so don't forget it." And "our own troubles seem never so large after we have listened with understanding and sympathy to the greater troubles of others." A juvenile correspondent who signed herself "Dimples" proffered the following piece of advice, which was doubtless the outcome of a vast experience: "For bad temperedness and depression, I have found it a good idea to have a cold wash and change of clothing." Though this book has been compiled for the benefit of business women, it is one which every employer, male as well as female, should study carefully, for it reveals the soul of a large class in the community.

MEDICAL SUBSCRIPTIONS AND INCOME-TAX RETURNS.

To the Editor of THE LANCET.

SIR,—For some months past we have been in communication with the Board of Inland Revenue with a view to obtaining subscriptions to certain medical societies allowed as an expense against the income of medical practitioners. Many inspectors of taxes have refused to pass these items, but in one case with which we have been dealing we have now received a letter from the inspector concerned from which the following is an extract: "With reference to previous correspondence, I am now advised that by recent Board's Order the subscriptions to the British Medical Association, London and Counties Medical Protection Society, and British Medical Protection Society may be allowed as a business expense." It would appear from the above that our efforts have been successful, and medical practitioners should note that any subscription paid to the above societies may be included in their expenses.

We are, Sir, yours faithfully,

HARDY AND HARDY,
Taxation Consultants.

292, High Holborn, London, W.C., June 3rd, 1924.

An Account
OF THE
TUBERCULOSIS OBSERVATION WORK OF THE MINISTRY OF PENSIONS.

Based on papers read before the Tuberculosis Society on March 14th, 1924,

By ALEX. SANDISON, M.B., B.C. Camb., B.Sc. Lond.,
ASSISTANT DIRECTOR OF MEDICAL SERVICES ;
AND
G. BASIL PRICE, C.M.G., M.D., F.R.C.P. Lond.,
DEPUTY COMMISSIONER OF MEDICAL SERVICES (TUBERCULOSIS).

I. Preface on Organisation.
By Dr. Sandison.

Accurate diagnosis of tuberculosis is at all times a matter of great importance, but to the Ministry of Pensions such accuracy is specially essential, for dependent upon the diagnosis of this disability is the acceptance or rejection by the State of a liability extensive both in time and in amount. I do not propose to discuss the questions involved in a decision as to whether or not an existing tuberculosis in an ex-Service man can be accepted as attributable to or aggravated by war service. Such problems of "entitlement," as they are technically termed, in allusion to the entitlement to pension which is involved, are peculiar to the Ministry and absorb a very material proportion of its time and work. Happy are they who need take no thought of such subtleties. Before, however, entitlement can be considered it is essential that the Ministry should know precisely what is the condition for which entitlement is claimed. The term "debility," for example, is one which covers a multitude of pathological conditions of which tuberculosis obviously is one. The private doctor, dealing with a case of debility accompanied by some prima facie evidence of past or present tuberculosis, can often act on the assumption that tuberculosis is the causal factor, and though he may not necessarily give a definite diagnosis of tuberculosis to the patient, he may yet prescribe general and special treatment which, if tuberculosis is really present, will certainly do good, but if it is not will do no harm and may quite possibly cure the debility without it ever being known what was the actual cause. Such treatment, though more or less empirical, is frequently abundantly justified by results. The debility departs, the patient rejoices, and the affair is over. If, however, the patient is an ex-Service man who claims that his debility is consequent on war service, the matter at once becomes much more complicated. Suppose "debility" as such is accepted as due to service, the State may then be committed to the responsibility of treating indefinitely a condition which is simply the common factor of almost innumerable pathological conditions and which may recur from time to time from totally different causes. If, however, a prima facie ætiology of tuberculosis is accepted, and entitlement is given definitely for tuberculosis, the State has then accepted responsibility for a condition of very serious portent and implication. Thus, as regards entitlement, true justice can only be done, to the man and to the State, by attaining the greatest possible accuracy of diagnosis.

It soon became apparent in the work of the Ministry that the existing diagnoses of tuberculosis in ex-Service men lacked in many cases that necessary precision. Tuberculosis was at times diagnosed during service on evidence which would not have been accepted had the necessary time and facilities been available to investigate it fully. Even a record of tubercle bacilli being found in the sputum could not always be accepted as gospel truth. On the other hand, disordered action of the heart, neurasthenia, malaria, pyrexia of unknown origin, were army diagnoses which not infrequently masked a true tuberculous condition.

Thus before the war had long been over there were numbers of pensioners with, on the one hand, an entitlement for a tuberculosis which did not exist, and on the other a lack of entitlement for a tuberculosis that did. Add to these cases the steady stream, not yet run dry, of those who submitted claims for entitlement for a tuberculous condition which revealed itself subsequent to discharge from the Service, and it needs little imagination to see that it became an urgent necessity for the Ministry to make sure that the most modern and efficient methods available were utilised for obtaining the evidence upon which entitlement for tuberculosis was to be based. Obviously the first line of defence was the tuberculosis service of the country, to which, in view of its existing extensive organisation and facilities, the function of treating the tuberculous "other rank" pensioner had been delegated by the Ministry. Tuberculosis officers were in direct charge of these pensioners, and to them, therefore, the Ministry applied for evidence as to the presence or absence of tuberculosis in individual cases. As time went on, however, three things became apparent.

1. The facilities for full and complete observation of doubtful cases of tuberculosis varied very greatly in different parts of the country, and true observation wards were rarely available.
2. Considerable divergence of opinion existed as to the relative value of different diagnostic criteria, and the "personal factor" of the tuberculosis officer could not be effectively equated.
3. Tuberculosis officers, not unnaturally, were inclined to attach special importance to an already existing diagnosis if it was recorded officially in army or pensions documents.

In 1920 the Ministry arranged for 100 cases taken at random of men pensioned for tuberculosis to be subjected to a comprehensive expert examination, and it then appeared that about one-third of these were wrongly diagnosed as tuberculosis. Other evidence, pointing to similar conclusions, accumulated from various directions, and finally, after consultation with the Ministry of Health, the Ministry decided to provide for itself full facilities for the complete investigation of doubtful cases of tuberculosis amongst pensioners. For this purpose, early in 1922, wards were allotted in certain Ministry hospitals throughout the country, the hospitals chosen being well equipped with laboratory and X ray facilities. The total number of beds so allotted has averaged over 200 for England and Scotland since that time. In Wales special arrangements were made with the Welsh National Memorial Association for observation to be carried out in their sanatoria.

It was an essential part of the scheme that the observation should be conducted in a uniform manner throughout the country, and that the duty of arranging for such observation and of making a definite decision on the evidence thus obtained should be placed in the hands of a small number of specially qualified medical officers whose methods and results could be coördinated through headquarters. Seven such officers (Deputy Commissioner of Medical Services, Tuberculosis) have been appointed, their activities covering England, Scotland, Wales, and Ireland. Their duties, however, are not limited to the control of these observation beds ; they act also as general liaison officers between the Ministry of Pensions and the tuberculosis officers of the country, and are more or less directly concerned in all that affects the pensioner, officer, nurse or man, who has, or who claims to have, entitlement for tuberculosis, pulmonary or surgical.

A time limit of 28 days is set for the period of observation, and the average stay of each case is about three weeks. Thus every three or four weeks for the past two years some 150 cases of doubtful tuberculosis have been systematically investigated by a standard routine by the Ministry, and the results recorded in a comparable manner. It will be seen that in this direction the Ministry of Pensions has been and is carrying on work which, in addition to its great value to the Ministry itself, is providing most valuable information for all tuberculosis workers and to an extent never previously accomplished in this country.

It is not as yet either possible or desirable to set out the total results of the work throughout the country, but the facts and figures which Dr. Price submits are fully representative of the results obtained by his colleagues elsewhere, and the deductions he makes from his experience are largely justified and strengthened by their experience also. The Ministry's regulations are, naturally enough, not easily understood by those who touch its work at the periphery only, and to whom it is neither a duty, nor can it be a pleasure, to seek to fathom the intricacies of pensions administration. Such intricacies are the inevitable accompaniment of so gigantic an organisation, started as it was in time of war and faced with problems hitherto unknown and with complications unpredictable. The Deputy Commissioners of Medical Services (Tuberculosis) are the interpreters to tuberculosis officers of these intricacies; in this liaison work they have been of real service. The duty and responsibility of the Ministry of Pensions as regards those receiving or claiming pension for tuberculosis is complementary and supplementary to that of the tuberculosis officer. The Ministry must satisfy itself that the diagnosis is clear because it is the authority that must meet the cost of pension and treatment if "entitlement" is granted; it must be the authority for deciding on "entitlement" since with it alone are the full war records of each case; and it must provide the necessary treatment when, as in the case of officers and in certain areas surgical tuberculosis cases, the treatment is not normally provided by the existing schemes of local health authorities.

II. REVIEW AND ANALYSIS OF CASES.

BY DR. PRICE.

Amongst discharged soldiers diseases of the respiratory system occupied a prominent position, as was indeed to be expected. The use of poisonous gases in warfare had introduced a new factor in the causation of respiratory diseases, and prolonged exposure in trench warfare through all seasons of the years, combined with periods of comparative inactivity in the worst conditions of climate and life, were important predisposing causes. A relatively large number of men were thus "invalided" for the sequelæ of gas poisoning, and for types of respiratory affections also common in civil life, particularly tuberculosis. In June, 1923, there were nearly 40,000 pensioners suffering from tuberculosis, including some 3300 non-pulmonary cases.

The symptoms of a depreciated physical state, loss in weight, chronic cough with sputum, reputed "coughing up of blood" (a statement which obtains in many cases a too ready credence), and on examination, the presence of slight physical signs—e.g., crepitations, probably more marked or persistent in one lobe of a lung than another—were common enough in these men returned from the war, and thus it is easy to understand that diagnoses of tuberculosis were made in a great number of cases. Hospital accommodation, moreover, was taxed in all directions at the time, and systematic observation was impossible for checking the diagnoses. In addition, medical opinion tended to assume that men who had suffered exposure to gassing would, a priori, be more prone subsequently to develop tuberculous infection. In men returning from the East, debilitated by malaria and dysentery, the transient chest symptoms, present in many on return to a colder climate and English winters, were viewed more gravely than after-experience proves to have been necessary.

Again, soldiers returning from abroad were anxious to be demobilised without delay, and a large number failed to make proper use at the time of discharge of the opportunity afforded for claiming consideration for disabilities they considered to be then present. Many, too, feeling comparatively fit on return, did not foresee the possibilities of a failure in health. Following the vicissitudes of civil life—unemployment and deprivation to some extent of the necessities of life—old symptoms returned, or slight conditions of ill-health became emphasised and more pronounced. A constant series of new claims therefore came to be considered; and though the lapse of time will eventually end these fresh claims, the Ministry must give full consideration to them, and their possible relationship to service. Many doubtful cases thus need to be investigated, and arrangements have been made for selected hospitals to provide accommodation for their adequate examination.

The pensioners admitted for this purpose from what is known as the London Region (bounded roughly by a line drawn across the map from the Wash to the Solent or Channel Islands) go to the Ministry of Pensions Hospital, Orpington, where 80 or more special observation beds are available as required, together with complete facilities for laboratory and X ray investigations. A visiting staff of specialists is also available for consultation.

It is proposed here: 1. To outline briefly the scope and methods of the investigations. 2. To give a brief analysis of the first 500 cases investigated, with comments on the factors of gassing, gunshot wounds of chest, and syphilis in relation to the incidence of tuberculosis and other chest disabilities. 3. To estimate and comment on the relative value of special methods of research; comparing the results of clinical, pathological, and X ray findings.

1. *Scope and Methods of Investigation.*

The importance of as thorough an examination as possible was quickly realised; any disabilities that might subsequently arise would then be more definitely dated as to time of origin, and the connexion or non-connexion with the invaliding disability more readily established.

The examinations are divided into three sections, all of which are carried on more or less concurrently: (1) Clinical; (2) pathological; (3) radiographical.

1. *Clinical Investigations.*—On admission the pensioner is kept in bed for the first four days, during which period rectal and mouth temperatures are recorded four-hourly. Subsequently, when the patient is up and about, the temperature (rectal) is taken only night and morning. An attempt has been made roughly to gauge the effects of exercise on body temperature, provided the case is suitable, by arranging for three exercise-temperature tests. During the warmer weather, 20 minutes fairly heavy work is provided, under supervision, in the grounds of the hospital, such as digging, rolling, or other equivalent. In unsuitable or cold weather, physical exercises are carried on in the gymnasium. Immediately on the completion of this exercise the men return to their ward, are kept in bed an hour, during which the rectal and mouth temperatures are taken at half-hourly intervals, until the temperature has reached a normal level; observations on the pulse and respiration are also noted.

Each case is under daily clinical observation by a resident medical officer who has had special experience in chest work and who makes full notes of his frequent examinations. The final clinical report is thus based not on a single observation, but upon a series of examinations, which are of great service in determining the persistence or transient nature of certain physical signs. Every region of the body is overhauled, and any symptoms, even apparently alien to the disability actually in question, are followed up to elucidate any possible inter-relationship. Thus, fractional test-meals, barium meals, examination of resting gastric juice for tubercle bacilli, sigmoidoscopic and cystoscopic procedure (including examination of ureteral urine) may all on occasion be required.

For the conclusions embodied in the final reports the Deputy Commissioners in Tuberculosis are personally responsible after their own examination of the man, and these reports are made after the clinical findings have been correlated with the findings from other departments, and the case viewed in the light of all available evidence.

2. *Pathological Investigations.*—When sputum is available, at least five examinations are made from the morning sputum, or from a 24-hour specimen to determine the presence of tubercle bacilli. As a rule the first test is made using the antiformin method, as in many cases the pensioners have had a fairly long journey, which may excite a slight rise of temperature and a freer expectoration of sputum. In addition, the complement-fixation test for tuberculosis is carried out, and the Wassermann reaction noted for purposes of control. Von Pirquet's tuberculin skin reactions are tried; tuberculin O.T. (human), as supplied by Burroughs and Wellcome, being used in dilutions of 1–10, 1–100, 1–500 with a control; special attention is given to the area and depth of infiltration resulting.

In making the film examinations for tubercle bacilli the possible presence of spirochætosis, mycelial or other infection is kept in mind. One case of nocardial infection, for instance, was found, presenting an interesting clinical state and peculiar sputum characters; the condition had for some years been regarded as tuberculosis. Elastic tissue fibres have rarely been found in the type of case under observation. Sputum albumin has been estimated as a routine observation, so that the results might be compared in parallel with other tests. The urine is fully tested at least twice, and if pus cells are present or urinary symptoms occur, the urine is also examined for the presence of tubercle bacilli. Tubercle bacilli have occasionally been found in the stools when absent from other discharges. Animal inoculation is occasionally required. Laryngological, aural, nasal examinations are made by the consulting laryngologist attached to the hospital.

Diagnostic tuberculin is not now employed. The risk of revival of an apparently arrested or quiescent infection cannot be ignored and the Ministry considered that such a risk was not justifiable.

3. *Radiographical Reports* from screen and film examinations are included in all cases.

2. *Analysis of 500 Cases Admitted for Investigation.*

While diagnosis of a suspected tuberculous lesion is, as a rule, the main problem confronting those responsible for the investigations, it is by no means the only one. Thus it is frequently stated that information is needed as to whether the patient has tuberculosis or has *ever* had it; if present, how long has it existed, and is the condition connected with service? It is appropriate here to point out that whilst a private doctor or even a tuberculosis officer can alter his diagnosis at will according to the variations in the evidence from time to time, the Ministry, once having accepted a definite diagnosis and granted an entitlement thereon, must require very definite contrary evidence before it can officially alter the diagnosis. Mere suspicion and doubt of a diagnosis are not adequate when considerable issues (often of a financial character) affecting the pensioner are involved.

Continued entitlement for tuberculosis does not imply necessarily that continued treatment is required, but simply that the pensioner has been accepted by the Ministry as one who has present, or has had past, disease. On the other hand, it is to be noted that a phrase is often found in reports from tuberculosis officers to the Ministry to the effect that a pensioner has no *active* tuberculosis, or has no evidence of *present* tuberculosis, and this, though probably not meant to imply "no past disease," is open to such interpretation. Misunderstandings at times have occurred, and these would be obviated if this kind of statement was amplified to make clear the opinion as to past disease. Of the 500 cases referred to, 243 had entitlement for pulmonary tuberculosis, and of these 37 had records of tubercle bacilli having been found at least once, the remaining 206 had been diagnosed on clinical grounds, and there were no records of tubercle bacilli having ever been found present in the sputum.

As will be best seen from the attached table eight out of the 37 were still T.B. +, and one was clinically active; 20 showed a quiescent condition, while in eight cases there were grounds for considering that the diagnosis should have been a non-tuberculous condition.

Results of Investigation.

A = Number of cases investigated.

* S = surgical.

As regards the 206 cases of pulmonary tuberculosis in which tubercle bacilli were never previously found, in 13 tubercle bacilli were discovered in the sputum, or in one or other of the body discharges. In one of these cases clumps of an acid-fast bacillus, considered to be the tubercle bacillus, were recovered from the resting juice of the stomach, though not obtained from the sputum. There are, of course, fallacies to consider in such a method, but, on the other hand, when correlated with other clinical and special evidence, the result may be of importance. Five other cases were clinically active, whilst 101 cases showed evidence compatible with quiescent or in some cases arrested disease. In 75 it was considered the diagnosis should be altered to chronic bronchial affections, associated with varying degrees of fibrosis, asthma, or bronchiectasis. Five had conditions probably of syphilitic origin, one of which had special (venereal disease) treatment in a civil hospital by arrangement and materially improved. Fibroid phthisis was the invaliding disability in 28; this condition seemed particularly common in men coming from the Navy, many of whom were stokers. In only one of this group were tubercle bacilli found whilst under observation, one had clinically active tuberculosis, ten were quiescent, and in 16 practically no alteration in the diagnosis was made.

Of 79 cases admitted under the labels of chronic bronchitis, bronchitis and asthma, bronchitis and fibrosis, bronchiectasis, &c., but in whom tuberculosis was suspect, three had tubercle bacilli in the sputum, one showed tuberculous activity, 23 gave evidence of quiescent foci, largely masked by secondary conditions, and in 52 the diagnosis remained as before.

Epitomising therefore: Of 243 cases admitted with reputed and "entitled" tuberculosis 21 still showed tubercle bacilli positive (9 per cent.), six showed activity (2·5 per cent.), 121 (50 per cent.) showed evidence of old quiescent or arrested lesions, while in 95 (33 per cent.) there was no clear evidence of present or past tuberculosis. The non-pulmonary tuberculosis cases numbered 23; of these ten remained unaltered in diagnosis, 13 were found non-tuberculous.

The various conditions (non-tuberculous) in which tuberculosis had been suspected make a lengthy list. The final results in the 500 cases are as follows :—

	Per cent.
Tubercle bacilli discovered in sputum or discharges (this includes ten surgical, decided on clinical grounds) ..	9·8
Active pulmonary tuberculosis, but no tubercle bacilli found	2·4
Quiescent or arrested pulmonary tubercle (the majority with secondary bronchitis and fibrosis)	35·8
Insufficient present evidence on which to diagnose tuberculous infection	52·0

Syphilitic Infection and its Relation to Chest Disabilities.

The Wassermann reaction carried out as a control to the complement-fixation test proved to be positive in 44 cases out of 500—that is to say, 9 per cent.; few of these showed overt symptoms of syphilis, though an actual history of past venereal disease was obtained from a good many. In these 44 cases, 41 had a double plus reaction, and three a single plus or weak reaction. Tuberculosis was present in ten of the 44, three had tubercle bacilli in sputum, one had active tuberculosis but the sputum contained no tubercle bacilli, six had quiescent tuberculosis, one had doubtful tuberculous or syphilitic lesion of the lung, seven had marked pulmonary fibrosis probably of specific origin, 18 had chronic bronchial conditions with fibrosis, most of these showed considerable debility, five had non-pulmonary lesions.

The object of drawing attention to this specific infection as being present in 9 per cent. is to emphasise the probability of it being a marked factor in the persistence of debility accompanying the various chest conditions. A few cases who have placed themselves under treatment, and whose histories it has been possible to follow up, have shown decided improvement in their chest disabilities.

Tuberculosis and Gassing.

The early gas attacks of the Germans began in April and May, 1915. Chlorine was the gas first employed, released from cylinders, and allowed to drift when a favourable wind was blowing. Later, in 1915 and in 1916, lacrymatory gas shells were also in use. In 1916–17 more lethal gases such as phosgene ($C.O.Cl_2$), chlor-methyl and trichlor-methyl-chloroformate, chloropicrin ($C.Cl_3NO_2$) and others were utilised, and in 1917–18 in addition mustard gas (di-chlor-ethyl sulphide) and various arsine compounds were used singly and mixed. Those mentioned are all lung irritants, and in one example also vesicant. The immediate results and the pathological changes resulting in intense œdema of the lungs, rupture of the alveolar walls, patchy emphysema and thrombosis of capillaries are so well known and described by Edkins, Shaw, Dunn, Winternitz, Soltau, and in the official history of the war, Vol. II., that no full reference here is needed. As regards later and remote effects, it is probable that more knowledge will be forthcoming. The French mention cicatricial changes in the lungs, bronchiolitis obliterans, and bronchiectasis as later after-effects; also local thrombosis in the lungs, or more remote organs such as the brain and kidneys.

Of 188 Canadians investigated four years after being gassed, 54 showed no ailment; 78 had irritable heart; 26 had bronchitis and asthma; 18 had neurosis; and 12 were not traced. No case of this series had proved pulmonary tuberculosis, though several showed prolonged low fever, loss of weight, profuse perspiration, similar to those termed by Achard and Flandin as pseudo-tuberculosis.

Reference has been previously made to the early predictions that tuberculous developments would be common in gassed cases, but general experience has negatived this presumption. In the analysis of the 500 cases under investigation it thus came rather as a surprise to find the incidence of proved tuberculous infection and quiescent disease was much higher than in the Canadian and other statistics. It must, however, be remembered that all the cases investigated at Orpington are selected cases, with lung symptoms, in whom tuberculosis is already suspected or had been diagnosed. Such figures as are here given would have, therefore, to be corrected against the incidence of tuberculosis in the average industrial population, and correlated with the percentage of tuberculosis in a sample series of all pensioners who had been gassed. The "gassed" cases numbered 92 out of the 500. They are divided into two groups: (1) in which official records prove the pensioner to have been admitted to hospital for effects of gassing; (2) when there was no official record, but the patient volunteered the statement that he had been gassed, but only requiring regimental treatment was not admitted to hospital, and was able to return to duty after a brief period. Obviously these cases were light and the gassing could hardly be expected to leave permanent after-effects.

Group 1. (70 Cases.)

	Cases.
Documentary evidence of tubercle bacilli in the sputum before this investigation	8
Tubercle bacilli discovered in the sputum for the first time while under observation	4
Evidence of tuberculosis (active) but T.B. negative ..	1
Apparently quiescent lesions and T.B. negative. (These probably correspond to the pseudo-tuberculosis cases of other writers)	17
Non-tuberculous conditions, principally bronchitis, emphysema, asthma	34
No chest disability	6

Group 2. (22 Cases.)

	Cases.
Evidence of active tuberculosis and tubercle bacilli were present in the sputum	3
Evidence of quiescent tuberculosis, T.B. negative ..	3
Various bronchial conditions (non-tuberculous)	15
No pulmonary disability	1

There is therefore a heavier incidence of positive and active cases in Group 1 as compared with Group 2.

In the total of 92 gassed cases 16 cases (17·4 per cent.) were active or had been suffering from active tuberculosis. Twenty cases, or 21·4 per cent., showed evidence of quiescent disease, but had always been, so far as records showed, T.B. negative.

The diagnosis in these cases is a matter of opinion, but in this series it would appear that 38·8 per cent. of gassed cases gave evidence of tuberculosis, active or quiescent. The fact already mentioned that the whole 500 cases investigated are "selected" probably explains this high figure, which cannot therefore be taken to apply to gassed cases as a whole. Of the 14 cases admitted for "effects of gassing" none showed active tuberculosis or positive sputum, two gave signs of quiescent disease, and 12 were suffering from non-tuberculous bronchial conditions. Previous to March, 1920, "gas" cases were included in the Ministry's statistics under the heading of "chest complaints," this heading also included tuberculosis and bronchitis, the total being 95,132 up to March 31st, 1920; from that date a further 2604 "gas" cases have been awarded pension.

It will readily be recognised, therefore, that the results obtained in these 92 cases suspected of having tuberculosis form no definite criteria as to the incidence of tuberculosis in the total number of gassed cases.

Gunshot Wound of the Chest and Tuberculosis.

Schuller's early experiments on animals demonstrated the apparently direct influence of traumatism in localising and developing tuberculosis in bones and joints. Achard, V. Friedländer and others, repeating these experiments under stricter conditions, came to different conclusions. The rôle of traumatism is generally considered to be limited in its relation to the development of tuberculosis. More recently Imber, Oddo, and Chavarnac in their "Accidents du Travail" have again drawn attention to the subject, and definitely consider that traumatism may induce by inoculation a localised tubercle, aggravate existing or latent tubercle, or even cause a generalisation of pre-existing tubercle. Severe and extensive injuries, they state, are not followed by tuberculosis nearly so frequently as injuries provoking less severe re-actions. War experience tends only in general to corroborate this view. They, however, quote Sergent, Bernard, and Challamel in support, and consider that wounds of the chest producing little immediate effects may several years later be the starting-point of pulmonary tuberculosis.

These considerations therefore lend interest to the 27 cases of gunshot wound of chest in our series suspected of having tuberculosis. I have grouped them into three classes.

1. Foreign body not retained (penetrating wound)	12
2. ,, ,, retained ,, ,, ...	8
3. Surface, non-penetrating wounds	7

In Group 1 the diagnosis of sequelæ of gunshot wound (chest) remained unaltered in five, in two evidence of active tuberculosis (sputum negative) was present, two showed evidence of quiescent (tubercle bacilli negative) tuberculosis, and three had broncho-fibrotic (non-tuberculous) conditions.

In Group 2 one case was found to have positive sputum, one showed quiescent tuberculosis, and three were of the bronchitic (non-tuberculous) type, while four remained unaltered in diagnosis.

In Group 3 one was tubercle bacilli positive, one quiescent, and five were unaltered in classification.

The frequent and persistent recurrence of hæmoptysis in these cases is a disturbing feature, and is the main cause for suspicions of tuberculosis being aroused. There are some clinical considerations with regard to hæmoptysis (recurrent) in gunshot wounds of the chest which are worth discussing. Unless there is an obvious irritant retained, the hæmoptysis in gunshot wounds of the chest tends to improve as years go by. It may be completely absent while the patient keeps at rest or uses a minimum of exertion. As soon as he tries to get about to live a more ordinary life and exposes himself to physical stress the hæmoptysis is apt to recur and is somewhat proportional in severity to the exertion apparently exciting it.

Tuberculosis, as these figures show, may supervene, and cases do occur which present very puzzling problems as to whether it is the tuberculous infection or other sequelæ of the original traumatism which are responsible for the hæmoptysis and existing condition.

3. *Relative Value of Clinical, Pathological, and Radiographical Evidence in Investigations of Suspected Tuberculosis.*

It has been a matter of considerable interest to compare, side by side, the clinical, pathological, and X ray evidence of tuberculosis in the 500 cases under observation. Apart from the presence of tubercle bacilli being demonstrated in the discharges, it was hoped that the complement-fixation test would be capable of development and prove to be a test comparable in certainty to the Wassermann. These hopes have not been realised to the extent hoped for, though the complement-fixation reaction may be decidedly helpful in suggesting the probable infection responsible for dubious clinical signs. At times, however, it is negative even when undoubted infection is present, or is perversely positive in apparently non-tuberculous cases. Besredka's antigen was used throughout; it has varied in sensibility at times, depending probably on questions of technique in preparation. This antigen is obtained by culture of tubercle bacilli in media containing yolk of egg. The four days' old culture is killed at 120° C. An emulsion is then prepared and shaken up so as to obtain a homogeneous preparation.

In the following analysis the degree of reaction has been classified as follows:—

Deviation.

(1)	Under 1 minimum hæmolytic doses	.. negative.
(2)	1–2 ,, ,, ,,	.. doubtful.
(3)	3–4 ,, ,, ,,	.. positive.
(4)	4–5 or over ,, ,, ,,	.. strong positive.

The end-results obtained are here quoted.

The reaction was obtained in 124 cases as follows:—

Strong Positive, 27. Eight of these were tubercle bacilli positive; 1 was negative as to tubercle bacilli, though showing active symptoms and signs; 15 had quiescent tuberculosis; and 1 was surgical tuberculosis; the remaining 2 were not considered to be tuberculous.

Positive, 77. Of these 9 showed tubercle bacilli in sputum; 7 were active, but no tubercle bacilli were demonstrated; 52 had quiescent disease (3 originally being tubercle bacilli positive); 1 was a surgical case (joints); 8 were not considered to have tuberculosis.

Doubtful Reactions, 20. Three were tubercle bacilli positive; 12 had quiescent or arrested conditions; 5 were not considered to have tuberculosis.

It is to be remembered that positive Wassermann reactions were *not* present to complicate the findings in these cases. The total result therefore is:—

Positive or Doubtful Complement-Fixation Reactions, 120. Twenty tubercle bacilli positive; 8 tuberculosis active, but tubercle bacilli negative; 79 quiescent, negative (2 surgical tuberculosis); 15 non-tuberculous.

Negative Complement-Fixation Reactions, 118. Five had tubercle bacilli positive; 10 had active clinical signs and symptoms of tuberculosis; 100 were considered to have quiescent tuberculosis; 3 cases of genito-urinary tubercle also positive.

These results give the following percentages as regards the presence of complement fixation:—

(*a*) In known pulmonary tuberculosis (tubercle bacilli present) C.F.T. was positive in 80 per cent. of cases.

(*b*) In clinically active pulmonary tuberculosis (tubercle bacilli negative) C.F.T. was positive in 44 per cent. of cases.

(*c*) In quiescent pulmonary tuberculosis (tubercle bacilli negative) C.F.T. was positive in 44 per cent. of cases.

(*d*) In clinically non-tuberculous conditions C.F.T. was positive in 10 per cent. of cases.

The complement-fixation reaction may be also positive in varying degree in non-tuberculous cases. In this connexion one case may briefly be quoted because of its special interest due to verification by post-mortem.

Pensioner C. was a case of a long-continued irregular pyrexia—wasting, indefinite pains and discomfort in chest and abdomen, with at times chest symptoms of minor degree. The complement-fixation reaction on repeated examinations was found strongly positive over a period of time. The associated clubbing of fingers, with slight pulmonary signs at one apex, and later rapidly developing signs at one base seemed indicative of tuberculosis. No direct demonstration of tubercle bacilli could be made, but in spite of most thorough investigation alternative causes of disease could not be recognised, or visceral lesions found. Originally, he had suffered from malaria, when on service in the East. At the post-mortem, actinomycosis of kidneys, liver, and base of lung was found; a small calcareous and caseous (tuberculous) gland was present near the appendix and a healed fibrotic apex (tuberculous) of one lung, showed old infection with tuberculosis.

The following are some conclusions, based on the present analysis, as to the value of the complement-fixation test with Besredka's antigen (other antigens, including Punch's method of preparation, have only been used in a very few cases):—

1. A strong positive reaction suggests a tuberculous infection, but the degree of reaction is not necessarily proportional to the clinical condition and may be pronounced with a quiescent state of disease. A persisting and strong positive reaction should cause the clinical signs and symptoms

to be carefully scrutinised if tuberculosis is not clinically definite. Single observations, while suggestive, cannot be regarded as conclusive. Variation in results does occur, if the test be repeated at intervals.

2. A positive (weak) result does not give any decided indication in favour of tuberculosis though it may be a link in evidence when the type of infection is dubious.

3. The presence of a positive Wassermann much impairs any deductions from a complement-fixation test unless the complement-fixation test is of higher value than the Wassermann.

Sputum albumin was estimated in most of the cases, the sputum was shaken with three parts water, filtered, and boiled with acetic acid. The degree of albumin present was of no real help in estimating the presence of tuberculosis, nor did its absence exclude quiescent conditions.

Von Pirquet skin reactions were consistently carried out in a large number of the cases, Koch's old tuberculin being used in dilution 1–10, 1–100, 1–500, with a control. A scarifier was used in applying it to the skin. No consistent results were obtained in relation to the complement-fixation test; often-times the results were mutually contradictory. The skin reaction was absent in a number of cases diagnosed as tuberculosis, active and quiescent, including several with tubercle bacilli in the sputum or discharges.

Cultures from the sputum in a number of cases in which the bronchitic condition was emphasised showed the presence of an anaerobe described by Castellani, Douglas, Thompson. In these cases, some of whom had to be retained for treatment afterwards, vaccines containing the anaerobe caused very considerable improvement while remaining in hospital.

Radiographic Findings.

With reference to radiographic findings, in 127 cases the reports provided evidence tending to corroborate the positive clinical findings of tuberculosis. In other 66 cases, however, in which the clinical findings showed the presence of tuberculosis (including six tubercle bacilli positive, and five active but tubercle bacilli negative), the radiographic reports did not indicate the presence of tuberculous conditions and the lungs were reported as having slightly or no abnormal features present. While the accessory value of these examinations is very valuable, to obtain maximum benefit from X ray findings it is desirable that:—

1. A more uniform nomenclature by radiologists should be in use, particularly in the meanings they attach to the much-abused word "fibrosis."

2. Fuller appreciation by the radiologist of the clinical aspect of the case and past history of the patient would often tend to prevent the apparent contradiction of clinical and radiographical evidence.

3. In collaborating for investigation it is well for one radiologist to be responsible for X ray findings so as to secure uniformity in the consideration of films. It is not unusual to find diverse reports on the same patient within a brief period of time, when different radiologists are concerned in the readings.

Perhaps in no part of X ray work does experience in reading chest films and screen work more greatly enhance the value of the reports. It is perhaps well to recognise that no case of pulmonary tuberculosis which has been already diagnosed on cogent evidence should be considered non-tuberculous because the X ray may not corroborate this finding.

In conclusion, while each section of the investigation may contribute valuable information and provide links in the chain of evidence, in the end it would appear that apart from finding tubercle bacilli in sputum or discharges reliance must chiefly be placed on clinical evidence.

We are indebted to the Director-General of Medical Services of the Ministry of Pensions for permission to publish these papers.

HYPERGLYCÆMIA AND GLYCOSURIA IN ACROMEGALY.

By ARTHUR W. M. ELLIS, M.B. Toronto,
M.R.C.P. Lond.

With Pathological Report by Prof. Hubert M. Turnbull, M.D. Oxf.

(*From the Medical Unit, London Hospital.*)

The discovery of insulin, with the resulting proof of the pancreatic origin of diabetes mellitus, has given an impetus to the study of the other forms of disturbance of carbohydrate metabolism which lead to glycosuria. Of these, one of the most interesting is the glycosuria which often accompanies acromegaly, a severe example of which is the subject of this report.

A Case Related.

J. S., female, aged 42, was admitted to the London Hospital Feb. 10th, 1921. The patient was a typical acromegalic. She first complained of headache in 1914. Enlargement of the extremities was first noticed in 1916. She was admitted because of unbearable headache and rapidly progressing optic atrophy with loss of vision.* Thirst was first noticed eight months before admission, it became intense, and her doctor discovered sugar in the urine. In spite of restricting her sugar intake, this thirst had persisted.

Condition on Admission.—The urine contained 10 per cent. of sugar and acetone bodies in large quantity; the blood-sugar was 0·43 per cent. Dietetic treatment was begun on Feb. 22nd, 1921, and the urine became sugar-free after three days' fasting. The diet was then gradually increased until by March 17th the patient was taking 83 g. of carbohydrate, 44 g. of protein, and 76 g. of fat, totalling 1200 calories. She was then transferred to the surgical ward for operation. Under intratracheal ether followed by intratracheal gas and oxygen anæsthesia, hypophysectomy was performed by Mr. Walton on March 19th, and a large soft pituitary tumour removed by the frontal route. Following operation the patient was desperately ill, with rapid pulse and shallow rapid respirations. She, however, gradually improved and made a slow but steady recovery. No symptoms suggesting coma occurred at any time and, in spite of the prolonged anæsthesia, the urine on the day following operation contained only a trace of sugar. Three days after operation the patient was put on a light diet containing milk, eggs, fish, bread, and potatoes; the urine remained free of sugar. On April 8th the blood-sugar was 0·15 per cent. The patient was discharged on April 19th, with instructions to avoid carbohydrate excess and to carry out frequent examinations of the urine for sugar. Prof. Turnbull's report on the tissue removed at operation will be found in an appendix to this paper.

The patient was next seen on July 8th, 1921. Her general condition was much improved; her headache much less severe, and her eyesight very much better. She said that she had been adding no sugar to her food at table but otherwise had followed an ordinary diet. The urine had been examined once or twice a week, sugar had never been detected. Her blood-sugar was 0·12 per cent.

Readmission to Hospital.—In May, 1922, the patient was readmitted. Her general condition was excellent, but she still complained of a gnawing sensation in the right side of the tongue, a burning sensation in the inner canthus of the right eye, a throbbing, stabbing pain in the right temporal region, and a dull, aching pain in the right sub-occipital region. She also complained of nasal obstruction. The patient had continued to take any food she fancied, but had not added sugar; she had continued the periodic examination of the urine but had never detected glycosuria. The blood-sugar on May 5th was 0·13 per cent. A submucous resection of the septum was performed, with removal of part of the right middle turbinate.

She was again admitted to hospital on Jan. 3rd, 1923. For some months she had referred the pains in the head to a lump in the right side of the neck, where a rounded swelling, suggesting a gland, could be felt deep in the right anterior triangle. There was no glycosuria; the blood-sugar was 0·15 per cent. On Jan. 4th Mr. Walton operated and discovered a rounded tumour $\frac{1}{2}$ in. by $\frac{3}{4}$ in. lying at the base of the carotid artery, deep to both internal and external branches and firmly attached to the artery. With some difficulty it was freed from the artery and surrounding tissue and removed entire. After removal it formed a pinkish-white rounded tumour of the consistency of a lymphatic gland and was, apparently, completely encapsulated. The patient made an uneventful recovery and was discharged from hospital on Jan. 17th. The report on the excised tissue, which proved to be a mixed neuroblastoma and embryonic neuroma of the carotid body, will be found in the appendix.

---

* A detailed description of this patient will be found in the report of the surgical aspects of the case by Mr. A. J. Walton, The Lancet, 1921, i., 1168.

On August 10th, 1923, the patient again reported for examination. She still complained of pain in the head and neck deep in "at the root of the tongue." Her general condition was excellent. The urine was free from sugar, but a sugar tolerance test showed the following definitely diminished carbohydrate tolerance: Blood-sugar before glucose, 0·14 per cent.; blood-sugar ¾ hour after 50 g. glucose, 0·27 per cent.; blood-sugar 2 hours after 50 g. glucose, 0·22 per cent.

At the time of writing, three years after the operation, the patient's condition is unchanged. She still complains of pain in the head and neck and has recently suffered from photophobia. Careful examination has failed to reveal any evidence of extension of the growth into the sphenoidal sinus or alteration in her physical state. It is clear that she is emotionally unstable and, to some extent, the victim of an unwise and excessive sympathy in her domestic circle. The urine is free from sugar, but there is some hyperglycæmia. A sugar tolerance test has shown results practically identical with those of the previous examination, a definitely diminished carbohydrate tolerance: Blood-sugar before glucose, 0·18 per cent.; blood-sugar ¾ hour after 50 g. glucose, 0·22 per cent.; blood-sugar 2 hours after 50 g. glucose, 0·23 per cent.

The glycosuria of acromegaly is usually small in amount and a cause more of curiosity than alarm. As will be seen by the case here reported, it may, however, attain the proportions of a true diabetes, and in the literature can be found reports of cases showing all the symptoms and complications of that disease. Observations on the blood-sugar in patients with acromegaly are difficult to find; in our patient a marked hyperglycæmia was present, the blood-sugar on admission being 0·43 per cent. Though ketonuria is stated to be rare in acromegaly, Froment[1] has been able to collect a dozen instances in the literature, in which death from typical diabetic coma has ensued. In our patient a well-marked ketonuria was present, the acetone bodies in the urine measuring 0·2 per cent.; no symptoms of ketosis were present; the plasma bicarbonate was 66. It is generally stated, perhaps on somewhat meagre evidence, that the glycosuria of acromegaly is singularly insusceptible to changes in diet; in our patient no support for this statement was found, the urine became sugar-free on fasting as rapidly as would be expected in a true diabetes of equal severity.

Various Theories Examined.

The severity of the diabetes in this patient and its relief following hypophysectomy stimulate a consideration of the nature of the disturbance of carbohydrate metabolism existing in acromegaly, and of the rôle of the pituitary body in its production. The recognition of the frequent association of acromegaly and glycosuria dates from a paper by Hanseman in 1897. Hanseman[2] analysed the reports of 97 cases of acromegaly, and called attention to the occurrence of glycosuria in 12. Hinsdale[3] in the following year reported 14 instances of glycosuria in 130 acromegalics, while Borchardt[4] in 1908 stated that analysis of the collected reports of 176 cases showed glycosuria in 63, and the presence of "alimentary glycosuria" in a further eight. Later studies, while not confirming the frequency of occurrence claimed by Borchardt, have established the common association of the two conditions. The demonstration by Goetsch, Cushing, and Jacobson[5] of the occurrence of glycosuria following handling and electrical stimulation of the pituitary body, and of the increased carbohydrate tolerance in animals after hypophysectomy demonstrated the influence of the gland on carbohydrate metabolism and supported the theory developed from clinical observations, that both acromegaly and glycosuria resulted from over-activity of the hypophysis.

The more recent investigations of Camus and Roussy,[6] of Aschner,[7] and of Bailey and Bremer,[8] have thrown some doubts on the correctness of this hypothesis. These observers produced destructive lesions of the nervous system in the region of the floor of the third ventricle. Care was taken to avoid injury to the hypophysis. They claim to have produced in this way, in animals, glycosuria, a polyuria simulating diabetes insipidus in man, and a condition of fat accumulation with an accompanying loss of secondary sexual characteristics, similar to dystrophia adiposo-genitalis. Camus and Roussy are of the opinion that these conditions, glycosuria, diabetes insipidus, and dystrophia adiposo-genitalis, are due not to disturbance of pituitary secretion, as has generally been contended, but to mechanical pressure on, or injury of, nervous centres in the base of the brain. Without minimising the importance of these observations, it can be stated that, as regards the origin of glycosuria, the evidence presented in support of this view is meagre. In none of the experiments, whatever the operative measure employed, was glycosuria, of a more than transitory character, set up, and nothing resembling the prolonged and severe glycosuria, seen in our patient, was ever produced. That there exist centres in the base of the brain which, when stimulated, lead by action through the sympathetic to increased breaking down of glycogen, and thereby transient hyperglycæmia and glycosuria, cannot be doubted. There is, however, little experimental evidence to suggest that a permanent diabetes can be produced in this way.

The clinical evidence is also against the hypothesis. If mere mechanical pressure on centres in the floor of the third ventricle were the factor responsible for glycosuria in acromegaly, then all tumours capable of exerting such pressure should equally produce it. There is much evidence to show that this does not occur. Thus Borchardt[4] states that in reviewing the entire medical literature from 1886 to 1908 he was unable to find a single case of hypophyseal tumour accompanied by glycosuria, unless acromegaly was also present. Froment[1] in a recent communication confirms this and states that in later literature he, likewise, has been unable to find examples of glycosuria in hypophyseal tumours unassociated with acromegaly. On the other hand, Anders and Jameson[4] have collected a number of instances of lesions of the pituitary body with glycosuria and without acromegaly. A careful analysis of these cases shows, however, that in the majority the glycosuria was transient or terminal, and associated with either marked intracranial pressure or injury to the base of the brain. Only one case in the series, that recorded by Sainton and Rol,[10] is really free from objection, and is insufficient to refute the claim of an essential relation between acromegaly and glycosuria. A stronger argument against the theory of a mechanical origin of the glycosuria than its association with acromegaly and its absence in other hypophyseal tumours is the fact that juxta-hypophyseal extra-sellar tumours and inflammatory exudates, though obviously most favourably placed for exerting pressure on the area of the brain in question, rarely lead to glycosuria.

A Possible Explanation.

It appears, therefore, that the available evidence is against pressure on nerve centres as the cause of glycosuria in acromegaly, and that the theory that these disturbances of metabolism are due to a disordered secretion of the pituitary body offers the most plausible explanation. The relatively satisfactory carbohydrate metabolism following removal of the hypophysis, in the case described above, suggests that in this patient the glycosuria was not due to pancreatic deficiency. How, then, can it be explained? A possible explanation is suggested by the experimental observations of Burn, and of Olmsted and Logan. Burn[11] has shown that in rabbits pituitrin markedly modifies the action of insulin, diminishing, or even preventing, the marked fall of blood-sugar which normally follows an injection of insulin in the fasting rabbit. In rabbits rendered hypoglycæmic by insulin, a rise in blood-sugar followed the subcutaneous injection of pituitrin, comparable to that resulting from the administration of glucose. Burn showed, moreover, that this effect of pituitrin was not due to an increased breaking down of glycogen, as occurs when adrenalin is injected, but was apparently an action directly antagonistic to insulin. The results of Olmsted and Logan[12] also support this idea of an antagonistic effect of the hypophysis on the action of insulin. Their experiments are very suggestive, but a careful analysis of their protocols emphasises the highly artificial conditions under which they were made, and reveals the short duration of their observations on the effect of insulin in decerebrate cats with hypophysis intact. Further observations on this interesting apparent antagonism between pituitrin and insulin are obviously desirable, for it would seem to offer a possible explanation of the glycosuria of acromegaly.

In the appendix to this paper Prof. Turnbull suggests that the pars intermedia was the site of tumour formation in all of the ten cases of tumour of the glandular portion of the pituitary he has studied. In the past an over-activity of the anterior lobe has been held responsible for the development of acromegaly, but if Prof. Turnbull's view is a correct one, an over-activity of the pars intermedia would appear the more probable explanation. Such a hypothesis is in keeping with the idea we have suggested, that the cause of glycosuria in acromegaly is an inhibition of insulin action by increased pituitary activity, for pituitrin, though usually considered an extract of posterior lobe, is really an extract also of pars intermedia, no separation of these two structures being attempted, or indeed possible, in the commercial preparation of the extract.

There is, then, a considerable amount of evidence associating glycosuria with glandular overgrowth and over-activity of the hypophysis, and some evidence of an antagonistic relation between this gland and its product and insulin. This leads to the attractive hypothesis that glycosuria in acromegaly is due to an inhibition of normal insulin effect by excess pituitary activity. An attractive hypothesis is, however, always a source of danger to the unwary, the ground we are treading is highly contentious, and the whole subject of the pituitary body and its function is still wrapped in uncertainty.

Summary.

A case of glycosuria in an acromegalic patient shows the following points of special interest: (1) Severe hyperglycæmia, the blood-sugar on admission being 0·43 per cent.; (2) the successful accomplishment, after adequate dieting, of a major operation of prolonged nature, and the occurrence of only transient post-operative glycosuria; (3) the disappearance of glycosuria and hyperglycæmia following hypophysectomy and, although diminished carbohydrate tolerance is still present, the absence of glycosuria three years after the operation; (4) histological evidence suggesting the origin of the tumour in the pars intermedia; (5) the occurrence of a tumour of the carotid body.

The suggestion is advanced that the glycosuria of acromegaly is due to an increased activity of the hypophysis, probably the pars intermedia, with a resulting interference with the normal action of insulin on carbohydrate metabolism.

APPENDIX.

Pathological Reports by Prof. TURNBULL.

1. *Pituitary Tumour.*

The specimen (S.D., 460, 1921) was received on March 21st, 1921, and consisted of several small fragments of very friable tissue, mixed with red clot, in formaldehyde solution. The largest fragment measured 1 cm. in diameter, and consisted of pin-head granules of grey tissue mixed with blood. Another consisted of a membrane of yellowish-grey tissue with one slightly granular surface. The remainder appeared to be small portions of clot.

Microscopic Examination.—The two larger portions and some of the smaller were embedded in paraffin, and sections were stained in Ehrlich's hæmatoxylin with eosin, Weigert's iron-hæmatoxylin with van Gieson's mixture, the Unna-Pappenheim stain, Jenner's stain, and the Weigert-Gram stain with neutral red. In the largest fragment small areas in which spheroidal epithelial cells are packed round capillaries are separated by similar but dissociated epithelial cells mixed with red corpuscles. In the fragments which resembled clot a few small groups of similar epithelial cells lie among red corpuscles. The membrane is curved. Its convex surface is smooth; the concave surface is ragged, and upon it are some groups of epithelial cells similar to those in the other fragments. The membrane consists of a dense fibrous tissue, which encloses narrow acini. The long axes of the acini are parallel to the outer surfaces of the membrane. They contain a variety of cells such as are found in the anterior lobe of the normal pituitary body. The main part of the tumour is extensively disintegrated by hæmorrhage, but evidently consisted originally of a solid mass of epithelial cells traversed by capillaries. The membrane corresponds to a cap of compressed anterior lobe, such as we have found upon similar tumours removed entire at necropsy.

The spheroidal cells in the large fragment and in the portions of clot measure from 7 to 11 μ in diameter, the usual size being 8 μ. The nuclei are round, ovoid, or, less commonly, ovoid and curved. In cells measuring 8 μ in diameter they measure 6 μ. Most of the cells appear to be degenerate, the nuclei usually being excentric, whilst the cytoplasm has a ballooned appearance, being stained deeply towards the periphery alone. The nuclei resemble in structure those of epithelial cells in the normal pituitary body. The cytoplasm is distinctly basophil in sections stained with the Unna-Pappenheim stain, and is faintly basophil in Jenner's stain, but in sections stained with hæmatoxylin and eosin and differentiated for long periods in tap water, it has a greater affinity for the eosin than hæmatoxylin. The cytoplasm does not contain granules with an affinity for Gram's stain. Among these cells are a very few giant examples, which measure about 17 μ in diameter and contain three or four relatively small oval nuclei.

Some groups of similar spheroidal cells are present upon the concave or inner surface of the cap of compressed anterior lobe. Some of these groups are continuous with cells in acini within the cap. The majority of the cells within the acini are polygonal, and are larger, measuring from 9 μ to 14 μ in mean diameter. There are a few giant examples; for instance, a spherical, eosinophil cell measuring 40 μ in diameter and containing 14 nuclei. The cells are almost all chromophil cells containing granules with an affinity for Gram's stain; the eosinophil type is in great excess of the cyanophil.

Summary and Interpretation.—The pituitary tumour consists of epithelial cells, and has arisen either in the pars intermedia or in the posterior portion of the anterior lobe, a cap of compressed anterior lobe being present. Histologically the tumour is benign, the cells being very uniform and typical in appearance. The cells are very like the small, basophil, chromophobe cells of the gland, but the cytoplasm appears to be stained more readily and to be less distinctly basophil. A definite acinar arrangement is not present, the cells forming a continuous mass traversed by capillaries. The tumour cannot, therefore, be regarded as a "hypertrophy," if this term be defined as "an increase in magnitude without alteration in histological structure." "Adenoma" would appear to be the most appropriate designation. But I have obtained at necropsy a histologically similar tumour, capped anteriorly by anterior lobe, in which the spheroidal cells infiltrated not only the meninges but the substance of the brain. In the absence, therefore, of evidence concerning the histological relations of the margins of the tumour to adjacent tissues, "carcinoma" cannot be excluded. The capsule of compressed anterior lobe shows that the tumour arose either in the posterior part of the anterior lobe or in the pars intermedia. Since the year 1911 nine other tumours of the glandular portion of the pituitary body have been examined microscopically in the Pathological Institute of the London Hospital; one was associated with typical acromegaly, whilst four others were accompanied by structural changes possibly acromegalic in nature. Four of these nine tumours were removed at necropsy, and in all four a cap of anterior lobe was present; five were removed by operation, and in three a cap of anterior lobe was found. In one of those in which no anterior lobe was found the sella turcica was purposely not cleaned out completely at operation; from the other very little tissue was sent for histological examination. The constancy with which these tumours were enveloped in front by a demilune of anterior lobe, often of large size, suggests that the pars intermedia was the site of origin. If the tumours had arisen within the anterior lobe, it is unlikely that they would all have occupied the same position. Additional evidence of origin in the pars intermedia was afforded by the absence of any normal remnant of that part of the gland and, in some tumours, by the occurrence of columnar cells or by the arrangement of the cells in long narrow processes.

2. *Tumour of Intercarotid Body.*

The specimen (S.D., 37, 1923) was received in formaldehyde solution on Jan. 5th, 1923. It was an oval mass of moderately firm consistence, and measured 2·6 × 1·8 × 1·5 cm. It was covered with a delicate membrane of white fibrous tissue, to which were attached many fibrous tags. The cut surface was yellowish-brown, and showed many pin-head and smaller rounded areas separated by narrow clefts. The mass was bisected along the long axis, and one half was embedded in paraffin.

Microscopic Examination.—The mass is composed of numerous, more or less round areas, in which a cellular centre is surrounded by a delicate fibrillar or, rarely, a dense fibrous tissue. Groups of these areas are separated by capillaries, or, more often, by wide capillary spaces. In the cellular centres of these areas the limits of individual cells can generally be distinguished. Such cells are usually spheroidal or polygonal. They measure in mean diameter from 6 to 13 μ, and their nuclei from 4 to 6·5 μ. The cytoplasm is homogeneous or very finely vacuolated. The nuclei have usually one diameter slightly longer than the other. They have a deeply stained, narrow membrane and a close network of delicate fibrils of chromatin, on which are many nodes; they contain one or two nucleoli. The nuclei of the smaller cells are more deeply stained. Sometimes the central cells are of spindle shape and greatly elongated, whilst their nuclei are of narrow, oval shape; in places the cells appear to be replaced by long cytoplasmic cords containing nuclei at intervals. The number of spindle cells does not appear sufficient to permit the majority of the spheroidal and polygonal forms being regarded as cross sections of spindles.

The fibrillar tissue in the periphery of the areas resembles glia closely. It contains a very few oval nuclei, round which cell bodies are seldom recognisable. The zone of fibrillar tissue is sometimes very narrow, and in a few spots is absent, so that the free central cells are separated from capillary spaces only by a layer of endothelial cells. Usually it is of considerable width. The differentiation between the central cells and the peripheral fibrillar tissue is often sharp, though processes from the cytoplasm of the most peripheral cells usually blend with the fibrils. On the other hand, very few of the central cells may be clearly differentiated, but almost the whole area may be occupied by cells intermingled and merged with glia-like fibrils. The denser fibrous tissue consists of collagenous fibres which are stained red by van Gieson's mixture. It contains long, narrow spindle cells, with narrow oval nuclei. It merges with the adjacent fibrillar tissue. This denser fibrous tissue is relatively rare. Definite nerve-fibres surrounded by a collagenous sheath are not recognisable.

The mass is surrounded by a capsule of dense fibrous tissue. But this capsule is not sharply differentiated; numerous chains of cells and fibrils pass into it, lying as a rule about vessels. These chains often consist of very long, narrow cells lying parallel to one another. Some of the chains appear to consist of parallel, multinucleate cytoplasmic fibres, but this structure cannot be recognised with certainty. The capsule contains also a few sharply defined bundles of nerve of normal appearance.

Summary and Interpretation.—The structure of the tumour resembles that of the normal intercarotid body closely, except that a glia-like tissue replaces the definite nerve-fibres of the normal structure. Owing to the omission of a suitable fixative it is, unfortunately, impossible to determine how many, if any, of the central, free cells are chromaffin cells. Their cytoplasm appears to be less liable to distortion by formaldehyde than that of chromaffin cells. Many of the cells are of elongated, spindle shape and resemble cells differentiating to form nerves. In places multinuclear cytoplasmic fibres appear to have been formed, though the presence of such fibres cannot be established definitely. Further, the glia-like tissue is similar to that seen in embryonic portions of tumours of nerve-fibres. The free spheroidal and polygonal cells may only represent the least differentiated stage of a tumour of nerve-fibres. The tumour is a neoplasm formed by neuroblasts. Many of these are certainly differentiating towards nerve-fibres; to what extent they are differentiating into chromaffin cells cannot be determined. These features indicate that the tumour is of the nature of a neoplasm. It is not a hyperplasia of chromaffin cells. It can be called a "mixed hypertrophy of the intercarotid body due to a simple neuroblastoma and embryonic neuroma."

(*Continued at foot of next column.*)

HÆMORRHAGIC DISEASE OF THE NEW-BORN.

WITH REPORTS OF SIX CASES.

BY NORMAN B. CAPON, M.D. LIVERP.,
M.R.C.P. LOND.,
HON. PÆDIATRIC PHYSICIAN, LIVERPOOL MATERNITY HOSPITAL;
HON. ASSISTANT PHYSICIAN, ROYAL SOUTHERN
HOSPITAL, LIVERPOOL.

MEDICAL publications have recently contained frequent references to the so-called hæmorrhagic disease of the new-born; and there have been numerous records of cases in which the cure of the disease has been ascribed to the injection of whole blood. In this communication an attempt has been made to present the important points encountered in a review of the available recent literature; and six cases, all of which occurred in the Liverpool Maternity Hospital during the past year, are recorded.

The dominant symptom of this disease is hæmorrhage, either internal or external, which begins most often between the second and fifth days after birth, and rarely lasts more than five days. Examples of hæmophilia, and of symptomatic neonatal hæmorrhage, due to causes such as syphilis, sepsis, icterus, enteritis, asphyxia and birth-trauma, are not properly included in a discussion of this syndrome.

Important Clinical Features.

Reference need be made only to those clinical features which are most important. Bleeding may be external or internal; the former may take place from the nose, mouth, vagina, urethra, bowel, or umbilicus. Melæna with, or without, hæmatemesis is the most frequent form. The blood is usually quite fluid, but occasionally clots are seen. They were noted in two of my cases. Anæmia is rapid; approximately one may assume that the loss of 1 oz. of blood by an 8 lb. baby corresponds to the loss of 1 pint of blood by an adult. Pyrexia is frequently noted (Charts 1 and 2); it is transitory, and is probably nutritional in origin—a view to which the careful charts given in Welch's[15] paper lend support. Anorexia and drowsiness occur when bleeding is severe; in milder cases the child takes the breast normally. There is rapid loss in weight, with only slow return to normal when the child recovers. In suspected cases presenting unusual signs and symptoms the possibility of internal hæmorrhage must be remembered.

Some observers, including Holt,[7] believe that the illness is self-limited, and that the natural tendency and course of many cases is towards cure. But the value of appropriate treatment is evidenced by the fact that before the introduction of treatment by blood-injection the mortality rate was 50 per cent. to 60 per cent.; while recent reports suggest that the present death-rate is about 10 per cent. to 20 per cent.; in several short series of observations it has been under 10 per cent.

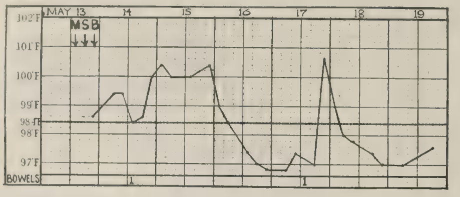
Ætiology and Pathology.

The ætiology and pathology of this disease present many difficulties, and it must be admitted that our knowledge is still very incomplete. Those who have looked for a gross pathological cause have pointed to the fact that on numerous occasions ulcers have been found in the gastro-intestinal canal, and especially in the first part of the duodenum. It is probable, however, that ulceration occurs in less than 50 per cent. of all examples of the hæmorrhagic disease ; a majority of the cases show only hyperæmia, congestion, and punctiform hæmorrhages of the gastro-intestinal mucous membrane. Occasionally small superficial erosions are seen. It is said that round-cell proliferation occurs in the submucosa.

During recent years attention has been deflected from the gross pathology of the mother and child, and has been centred upon the complex subject of blood-coagulation in infancy ; and it is now generally accepted that the fundamental cause of the hæmorrhagic disease of the new-born is to be found in a fault in the chemistry of the blood. My own observations are incomplete in this respect, for in my cases the blood was not specially studied. Rodda[13] has shown that in the normal infant there is a prolongation of the coagulation-time and bleeding-time from the first to the fifth days of life, and that after the fifth day there is a gradual return to the normal, which is reached on the tenth day. It may be that in the cases of hæmorrhagic disease there is an exaggeration of this normal feature ; for Rodda (loc. cit.) noted that hæmorrhage occurred when an abnormally prolonged bleeding-time accompanied an abnormally prolonged coagulation-time. But Rodda (loc. cit.) and Lucas and his associates[11] noted that prolongation of coagulation-time, when accompanied by a bleeding-time of normal duration, may exist without the onset of hæmorrhage. It is probable, therefore, that at least two types of hæmorrhagic disease occur in neonatal life :—

CHART 1.



Temperature chart of case of melæna neonatorum, born May 12th, 1923. Female, weighing 7 lb. 14 oz. at birth.
M = melæna began. S = 10 c.cm. horse serum intramuscularly. B = 10 c.cm. maternal blood, intramuscularly and subcutaneously.

(1) In this class there is a prolongation of coagulation-time, which may be due to excess of antithrombin, but is more probably ascribable, in accordance with the findings of Gelston[5] and Whipple[16] to deficiency of prothrombin. This deficiency is believed to be produced by a qualitative blood-platelet defect.

(2) In this class there is a prolongation of bleeding-time. In these cases a clot is formed, but it does not adhere to the edges of the breach in the vessel wall. Perhaps one might say with greater accuracy, that although clotting occurs in the main wound, thrombosis in the fine vessels adjacent to the wound is absent. Examples of this type have been variously ascribed to deficiency or defectiveness of prothrombin, of blood-platelets, and of thrombokinase.

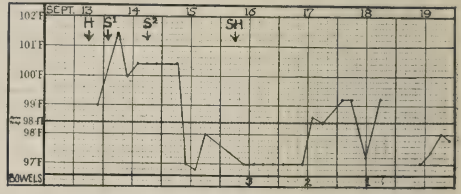
Influences of a more general nature have been regarded from time to time as possible causes of the hæmorrhagic disease ; but it is unlikely that the age of the mother, her obstetrical history, the intra-uterine age of the child, the character of the labour, the sex of the infant, or the use of anæsthetics during labour have any bearing upon the condition under discussion.

Treatment.

The best treatment is to administer whole blood to the infant. No matter whether we consider the disease to be due to deficiency of prothrombin, or of platelets, or of fibrinogen, or of thrombokinase, whole blood will supply the deficiency. If we accept Howell's[8] theory of blood coagulation, and believe that the hæmorrhagic disease is caused by excess of antithrombin, it is probable that the injection of whole blood will neutralise this antibody. Furthermore, whole blood probably stimulates the neonatal tissues to produce the substance which was previously deficient or absent ; and it certainly helps to make good the loss of fluid by hæmorrhage.

Unless the bleeding is very severe at its onset one is justified in giving whole blood by the subcutaneous or by the intramuscular route at first. The dose to be administered will depend upon the findings at clinical examination ; in a case of average severity it is probably wise to begin by injecting 20 c.cm. of blood (either citrated or not), obtained from the father, mother, or other donor by puncture of one of the antecubital veins. If hæmorrhage does not cease within two hours the injection should be repeated.

CHART 2.



Temperature chart of case of hæmatemesis neonatorum, born Sept. 11th, 1923. Male, weighing 7 lb. 14 oz. at birth.
H = hæmatemesis began. S^1 = 10 c.cm. horse serum subcutaneously. S^2 = ½ drachm orally. SH = slight hæmatemesis.

When the infant fails to improve speedily with this treatment, no time should be lost in resorting to intravenous transfusions, for, as Holt (loc. cit.) has emphasised, the fatal cases rarely survive more than three days, and often less than one.

Two important points must now be considered : First, whether blood-grouping is necessary ; and, secondly, the choice of vein into which the injection is to be made. With regard to the former, there is evidence in the important papers of F. B. Chavasse,[2] W. M. Happ,[6] and B. B. Jones,[9] that the blood-group is frequently established in early infancy, and that the mother and her infant may belong to incompatible groups. These findings imply that transfusion without preliminary grouping is an unjustifiable procedure. Biasi,[1] however, has recently shown by "typing" the bloods of 100 mothers and their children, and by cross-testing the bloods of mother and child against each other, that in no case were the maternal corpuscles agglutinated by the serum of the infant. He found this to be true even when the bloods of mother and child belonged to incompatible groups. Cherry and Langrock[3] in the course of somewhat similar investigations had obtained results parallel with those of Biasi. These findings confirm the experience of most clinicians, including Falls[4] and Pearce,[12] that preliminary "typing" of the blood is unnecessary.

The second important point is the selection of a suitable vein into which the injection may be made. If there is a fairly large external jugular vein, the operation should not present much difficulty. This route has been used with success by Falls (loc. cit.), Lapage,[10] and others. The superior longitudinal sinus is favoured by some. The head of the infant must be held firmly by assistants, and the needle introduced as far posteriorly as possible in the anterior fontanelle, to a depth of about three-eighths of an inch. It is a route which may be dangerous, but ill-effects are unlikely if the operator remembers that when the point of the needle is in the sinus the transfused blood should flow with the very slightest pressure on the syringe piston. Sidbury[14] recommends injection into the umbilical vein if the infant is not more than four days old.

In all cases the blood should be citrated (using 10 c.cm. of 3 per cent. sodium citrate solution to 100 c.cm. of blood), and should be injected at body temperature. The volume injected should depend upon the clinical condition of the infant. Cherry and Langrock (loc. cit.) state that 60 to 75 c.cm. of blood are approximately sufficient to supply the infant with the necessary substances to promote clotting and to replace the cellular elements lost by hæmorrhage. Others have used even larger doses; but it is probable that the coagulation defect in the child can be remedied by much smaller injections. Horse serum and human serum have been used, and have frequently proved efficacious; but they must be fresh, because thrombin is fairly rapidly transformed to inert metathrombin. It is obvious that serum treatment cannot supply fibrinogen; it will be useless in cases due to deficiency of this substance.

It is unnecessary to emphasise the importance of employing any surgical treatment which may be indicated for the control of hæmorrhage, for instance, from a bleeding umbilical vessel. Shock caused by severe blood loss may require intravenous or subcutaneous injections of normal saline solution. Rectal injections of 5 per cent. glucose solution have also been used for this purpose.

Case Notes.

The brief notes of my own cases are as follows:—

CASE 1.—Mother aged 28. One previous pregnancy, ending in miscarriage. Duration of present pregnancy: $39\frac{4}{7}$ weeks. Induction of labour on account of disproportion. Normal vertex delivery in the right occipito-anterior position. Duration of labour: $13\frac{3}{4}$ hours.

Infant: Female. Weight: 7 lb. 14 oz. Onset of melæna $26\frac{1}{4}$ hours after birth. Severe hæmorrhage, with pallor, yawning, and dry mouth. Weight fell to 7 lb. 5 oz. on the fifth day; increase began on the eighth day. Uneventful recovery. (See Chart 1.)

Treatment.—(1) Horse serum, 10 c.cm., intramuscularly; (2) maternal blood (citrated), 10 c.cm., intramuscularly and subcutaneously. An attempt to inject maternal blood into the superior longitudinal sinus was unsuccessful.

After-history.—The infant is now 7 months old. Weight: 18 lb. She is still pale, but otherwise normal.

CASE 2.—Mother aged 22. One previous pregnancy, ending in miscarriage. Duration of present pregnancy: 36 weeks. The mother suffered with albuminuria, œdema, and headaches during the pregnancy. Labour: normal vertex delivery in the left occipito-anterior position. Slight post-partum hæmorrhage. Duration of labour: 33 hours.

Infant: Premature female child. Weight: 4 lb. 7 oz. Onset of umbilical hæmorrhage 120 hours after birth. Copious bleeding; pallor; yawning. Spasmodic spurting of blood from an umbilical artery. Formation of clots was noted. Umbilical cord separated on the eighth day. By the ninth day the weight had fallen to 3 lb. 14 oz., but the infant recovered in spite of an attack of enteritis.

Treatment.—(1) Cord-stump ligatured with catgut: adrenalin solution (1/1000), and tannic acid applied to umbilicus, which was covered with a well-secured pad; (2) maternal blood (oxalated), 2 c.cm., injected into superior longitudinal sinus; (3) maternal blood (oxalated), 18 c.cm., intramuscularly in two separate injections of 10 c.cm. and 8 c.cm. respectively.

After-history.—The infant is now 15 weeks old, and weighs 8 lb. 5 oz. She has a slight umbilical hernia, and is pale. Her general health is fairly satisfactory, but she is obviously of poor physique.

CASE 3.—Mother, aged 37, had had three previous normal labours. Duration of present pregnancy: 40 weeks. Induction of labour on account of disproportion. Normal vertex delivery in the left occipito-anterior position. Duration of labour: $2\frac{1}{6}$ hours. The mother was removed to an asylum suffering with puerperal insanity.

Infant: Male. Weight: 7 lb. 14 oz. Onset of melæna and hæmatemesis 43 hours after birth. Severe hæmorrhage of short duration. Weight fell to 6 lb. 5 oz. on the eighth day. Uneventful recovery. (See Chart 2.)

Treatment.—(1) Horse serum, 10 c.cm., intramuscularly; (2) horse serum, $\frac{1}{2}$ drachm, orally; (3) calcium lactate, 3 gr., every four hours for three days.

After-history.—The infant is now 13 weeks old and weighs 13 lb. Apart from slight pallor, the child is healthy.

CASE 4.—Mother aged 34. No previous pregnancies. Duration of present pregnancy: 40 weeks. Normal vertex delivery in the left occipito-anterior position. Duration of labour: 9 hours.

Infant: Female. Weight: 6 lb. 5 oz. Onset of hæmatemesis and melæna 24 hours after birth. Severe bleeding, with pallor and dryness of the mouth. Weight fell to 5 lb. 5 oz. on the fifth day; afterwards, steady gain. Uneventful recovery.

Treatment.—(1) Horse serum, 10 c.cm., intramuscularly in two separate injections of 5 c.cm. each; (2) maternal blood (citrated), 30 c.cm., intramuscularly in three separate injections of 10 c.cm. each; (3) liquor adrenalini (1/1000), 1 minim, orally every two hours for 48 hours.

After-history.—The child is now 2 months old. Weight: 8 lb. 13 oz. She is still pale, but is otherwise normal.

CASES 5 and 6.—Mother aged 38. Five previous normal labours. Duration of present pregnancy: $37\frac{4}{7}$ weeks. Albuminuria, vomiting, and œdema, probably due to chronic renal disease, occurred during the pregnancy. Labour: twin infants; both presented by the breech, and were delivered in the left sacro-anterior position. Duration of labour: $4\frac{1}{2}$ hours.

Infants.—CASE 5.—Premature female child. Weight: 5 lb. 4 oz. Onset of hæmatemesis and melæna $49\frac{3}{4}$ hours after birth. Bleeding of moderate degree. The infant became extremely feeble, and on the sixth day of life the respirations became laboured and rapid, and the child collapsed. The temperature rose to 100° F., and on the morning of the seventh day it was 101·8°. Though extremely emaciated and weak, the child gradually recovered. On the eighth day the weight was only 4 lb. 2 oz. The infant was too feeble to suck; breast-milk was expressed and given in a spoon. Sherry-whey was also used.

Treatment.—(1) Paternal blood (citrated), 46 c.cm., intramuscularly, in five separate injections of 4 c.cm., 12 c.cm., 10 c.cm., 10 c.cm., and 10 c.cm. respectively; (2) horse serum, 4 c.cm., intramuscularly; (3) maternal blood (citrated), $1\frac{1}{2}$ c.cm., intravenously (superior longitudinal sinus), $8\frac{1}{2}$ c.cm. intramuscularly; (4) liquor adrenalini (1/1000), 1 minim, two-hourly for 48 hours.

After-history.—The infant is now 6 weeks old. She is pale and feeble, and weighs only 5 lb. 14 oz. Progress fairly satisfactory.

CASE 6.—Premature female child. Weight: 5 lb. 2 oz. Onset of hæmatemesis and melæna $43\frac{1}{4}$ hours after birth. Very severe hæmorrhage, with collapse. The infant died 23 hours after the bleeding began. Mr. J. St. G. Wilson kindly performed the autopsy. He found small superficial erosions of the gastric mucous membrane; there were no definite ulcers in the gastro-intestinal tract. No spirochætes were found in sections of the liver, lungs, spleen, suprarenals, and kidneys.

Treatment.—(1) Horse serum, 5 c.cm., intramuscularly; (2) paternal blood (citrated), 30 c.cm., intramuscularly in three separate injections of 10 c.cm. each; (3) subcutaneous saline injections; total volume, 70 c.cm.

Comments.

There were no cases of hæmophilia in my short series. With one exception, the infants were females, and the family histories did not reveal any "bleeders." In no case was there any reason to believe that hæmorrhage was secondary to some gross underlying cause, for instance, syphilis or sepsis. The average age when hæmorrhage began was 51 hours. In Case 2 the maternal blood was prevented from clotting by the addition of the minimal amount of potassium oxalate necessary for this purpose. Although the quantity of oxalate employed was too small to cause any toxic effects, accidents might happen with this procedure. On the other hand, the citrate method is quite safe, and is equally efficacious. In Case 3 a small dose of horse serum and calcium lactate were both given orally; it is very doubtful, however, whether either of these treatments possess any value.

I wish to express my thanks to Miss M. H. F. Ivens and to Dr. J. H. Willett, honorary surgeons to the Liverpool Maternity Hospital, for permission to publish these cases.

VITAMIN-A DEFICIENCY IN DENMARK AND ITS RESULTS.[*]

By E. WIDMARK, M.D.,
PROFESSOR OF MEDICAL AND PHYSIOLOGICAL CHEMISTRY IN THE UNIVERSITY OF LUND.

Have we any reason to fear that our food is too poor in vitamins? Can one observe a deleterious influence on the health of the people which one could ascribe to under-feeding with vitamins? These are practical problems of the greatest importance which have emerged from the recent investigations on the physiology of nutrition.

In those countries where beri-beri and scurvy are common diseases the deficiency in vitamins and its effects are obvious. In those countries, however, we are dealing with a population which, as a rule, lives on such an extremely monotonous diet that the cause of the vitamin deficiency can be demonstrated without difficulty. It is more difficult to determine to what extent a deficiency in vitamins may affect the health of the community in those countries where the diet is more varied. The question has arisen whether such a deficiency may occur under normal conditions in the civilised nations of Europe and America.

This question has been repeatedly discussed during the last few years. Some writers have certainly exaggerated the importance of the possible vitamin deficiency to which they have attributed as an immediate cause a whole series of the most various diseases and conditions of debility. The opposite extreme has been the complete neglect of considering the possibility of a vitamin deficiency. It has been asserted that if only the diet is sufficiently varied and contains the necessary number of calories the supply of vitamin regulates itself.

On the whole, the discussion has not reached any definite result on account of the absence of definite facts. We do not know enough about the actual demand in vitamins by the human organism. Moreover, our knowledge of the amounts of the different vitamins in our articles of food is not sufficiently exact to establish a calculation of the proportion between vitamin requirements and vitamin supply. For the present one is therefore compelled to deduce the occurrence of vitamin deficiency from the occurrence of such diseases which can be caused by vitamin deficiency.

Xerophthalmia and its Cause.

The observation of the Danish ophthalmologist, Olaf Blegvad,[1] on the occurrence of this eye affection in Denmark has given us very important information on the vitamin economy in that country.

Xerophthalmia is an eye disease which occurs particularly in the children of about a year or less; occasionally it occurs also in adults. The disease is preceded as a rule by loss of weight of the child. The disease is essentially a general disturbance of nutrition; the eye affection is only a partial symptom which occurs rather late in the development of the disease. The cornea has a dried appearance, the conjunctiva and eyelids swell and are inflamed; in the later stages of the disease the cornea shows definite lesions which break through the latter and then the whole eyeball is filled with pus. If the disease runs through all these stages complete blindness is the result. In adults the disease is arrested as a rule in an early stage, which is characterised by a slight inflammation and dryness of the cornea. This early stage is also associated with a peculiar alteration in the power of vision of the patient—hemeralopia or night-blindness. The vision of the patient is normal during the day, but as soon as dusk begins his vision suddenly is very bad and only becomes normal again with daylight.

The symptoms which we have described are associated with a whole series of complications. A very characteristic feature is the slight resistance of the patient against infections of different kinds. For 165 cases collected by Blegvad, the following complications are recorded: Pneumonia, 63; bronchitis, 45; pyuria, 42; otitis media, 30; nasal catarrh, 26; subcutaneous abscesses, 4.

Xerophthalmia, or "dystrophia xerophthalmica," as the whole symptom-complex was called by Blegvad, is on the whole a relatively rare disease. During the 12 years 1909–1920 Blegvad has collected in the whole of Denmark 434 severe and 148 light cases. The disease is more common in Denmark than in any other country from which statistical data can be obtained. Only in Japan has the disease reached the same frequency as in Denmark; in Sweden it practically does not occur at all.

During the last decennium xerophthalmia in Denmark increased in frequency. In fact, it has become there one of the main causes of blindness in children. Formerly, venereal infection was the common cause. This has now been replaced by xerophthalmia. Now the same disease can be produced in animals experimentally, if one excludes the fat-soluble vitamin A from the food. Between the xerophthalmia of children and that of the experimental animals no difference can be established either clinically or anatomically, and the investigations of Blegvad prove conclusively that the xerophthalmia in man is caused by a deficiency in vitamin A. He shows that the food in the overwhelming number of cases of the disease in children was poor in vitamin A; that in those cases where the vitamin deficiency in the food could not be demonstrated, other conditions were present which would cause a deficient absorption of vitamin A by the organism; that the variations in the number of cases run parallel with the corresponding variation in the supply of vitamin A which was available for consumption to the people as a whole; and lastly, that the poorer the food was in vitamin A, the shorter was the period during which a child could live on that food before the disease set in.

Xerophthalmia is not the only Effect of the Deficiency in Vitamin A.

Everybody who has experimented with the effect of food poor in vitamin A or free from any vitamin A on rats must have observed that the general condition of the animals suffers long before the eye disease appears. In young animals the growth stops almost always, their fur gets rough, they easily show infections of various kinds. If the vitamin deficiency is not complete no eye disease appears at all, and only the general condition of the animal suffers. Adult females breed badly; if they become pregnant they show a great loss of weight, and often eat several or all of the new litter. They are not able to nourish

---

adequately their young, and the mortality among the latter is great.

As the result of the experience gained from these experiments on animals, it follows necessarily that there must be in a population in which xerophthalmia occurs a much larger number of cases in which the deficiency in vitamin A, without producing the eye disease, is the cause of a diminished resistance against infections, of general debility, and of malnutrition.

We shall see from the following that this expectation is fulfilled, and it is for this reason that we must ascribe to this relatively rare disease such an eminent importance. The cases of xerophthalmia are recorded and treated in hospitals where an abundant supply of vitamin A in the form of cod-liver oil and full milk as a rule produce a cure. These cases are the most obvious indication of the vitamin deficiency, but apart from these cases there are probably a whole army of patients whose diseases get other names: disturbances of nutrition, pneumonia, bronchitis, rachitis, and so on, and for whom it was really the deficient intake in vitamin A which was the cause of their succumbing to the diseases. The investigations of Blegvad have given us the first certain proof of the occurrence of an under-feeding in vitamin A on a very large scale. It is a proof which cannot be denied even by those who believe only in the power of the calories and doubt the importance of the vitamins for the health of the people.

The Cause for the Occurrence of Xerophthalmia in Denmark must be looked for in an Excessive Export of Butter.

One is naturally inclined to ask why the vitamin-A deficiency has shown itself more distinctly than in any other country, not affected by the war, in Denmark, which to us in Sweden, at any rate, has always appeared as a country "flowing with milk and honey." No country in the world has proportionately to its population such a highly developed dairy industry as Denmark. This has become the main industry of the country, and it is on it that the wealth of the country mainly depends. The dairy products butter, cream, and partly also cheese, are the foodstuffs richest in vitamin A, and when they are exported Denmark also exports its vitamin A. This has occurred to such an extent that the whole population of the country has suffered. This important relationship has not been considered in great detail by Blegvad in the paper referred to above. I should like, therefore, to throw more light on the significance of this export on the occurrence of xerophthalmia in Denmark on the basis of a few statistical data.

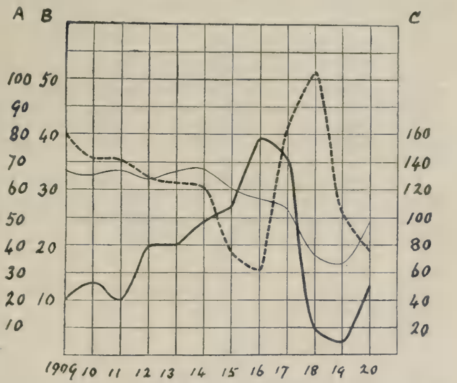
TABLE I.—*Relation Between the Milk Fat Consumption in Denmark and the Frequency of Xerophthalmia.*

Year.	Milk fat produced and imported.	Milk fat exported.	Milk fat consumption in the country.		Number of cases of xerophthalmia.
			Total mill. kg.	Per day and person.	
	Mill. kg.	Mill. kg.		g.	
1909	132·9	93·4	39·5	40·0	20
1910	130·1	94·6	35·5	35·6	26
1911	133·0	97·3	35·7	35·3	20
1912	128·7	95·6	33·1	32·3	40
1913	133·8	101·4	32·4	31·2	40
1914	133·2	101·3	31·9	30·4	48
1915	121·5	102·3	19·2	18·1	53
1916	113·8	97·4	16·4	15·3	78
1917	106·7	62·1	44·6	41·0	71
1918	71·9	15·2	56·7	51·5	9
1919	66·4	37·6	28·8	26·2	4
1920	98·8	77·4	21·4	18·9	25

In Table I. I have calculated from the number of cows and the average yield of milk the production in Denmark of milk fat, expressed in million kilogrammes of butter per annum. It has been assumed in this calculation that 26 kg. of milk yield 1 kg. of butter. For the years 1909–14 these figures have to be supplemented by the amount of milk imported into Denmark. After 1914 this import can be neglected in the calculation, since after that date it was practically stopped. These figures are given in the second column. In the third column is the export of milk fat from Denmark expressed in the same way. The export of cheese is here not calculated, as it is at present difficult to compare the vitamin content of cheese with that of butter. The figures for the export are therefore certainly too low.

In the fourth column of Table I. is given the difference between the figures of the two preceding columns—that is to say, the amount of milk fat consumed by the people in the country. In the second half of this column these figures have been calculated for the daily consumption per individual in grammes. The last column contains the cases of xerophthalmia as collected by Blegvad. The table is illustrated by Fig. 1. The thick line gives the cases of xerophthalmia, the thin line the production in milk fat, and the broken line the consumption per individual.

FIG. 1.



- - - - - Consumption of milk in grammes per day (Col. B).
▬▬ Cases of xerophthalmia (Col. A).
——— Production and import of milk fat in million kg. (Col. C).

It shows at once that the consumption of milk fat before the war and until 1916 inclusive has steadily declined so as to reach very low values in that last year. At the same time, the number of cases of xerophthalmia reached their maximum in that year—1916. Then there was a complete change. In the end of 1917, during 1918, and partly also during 1919 the export of butter was forbidden. In spite of the fact that the production of butter during that time decreased, much more milk fat was consumed in the country than in the years before the war. Xerophthalmia disappeared almostly completely, but reappeared in 1920 when the export of butter began again.

During the whole period Denmark has, therefore, suffered from its export of vitamin A, except during certain years of the war when the consumption reached 40–50 g. of milk fat per day and person.

The Vitamin Store in Sweden.

Since xerophthalmia is practically unknown in Sweden one must conclude, if the preceding deductions are correct, that the consumption in milk fat in Sweden is greater than in Denmark. This seems indeed to be the case. Statistical figures which have been collected for the consumption in articles of food in the poorer households during the years of the war 1914–18, show that the daily consumption during 1914 was on an average 52 g. of milk fat per member of the family, and during 1917, 53 g. The corresponding figures for Denmark are 30·4 g. and 41·0 g. per person. It must also be taken into consideration that the figures for Sweden refer only to the poorer families, while the figures for Denmark represent the average values for the whole population. In reality the difference is, therefore, much greater.

Two Additional Causes of the Vitamin Deficiency: Consumption in Margarine, and the Feeding of Cattle.

It is clear, therefore, that the export of butter from Denmark is really the immediate cause of the vitamin deficiency. The population naturally looks for a substitute for the butter; this substitute is margarine.

Dr. Blegvad makes here the following comments. Formerly all adult people in Denmark consumed rather large quantities of butter. During the last few years, however, butter has been replaced by the cheaper substitute—margarine, which is used especially by the economically less well situated population. At the beginning margarine was prepared from animal fat, which contains small amounts of vitamin A, but during the last years the animal margarine has been replaced more and more by vegetable margarine, since the latter can be manufactured more cheaply and tastes better than the animal margarine. The vegetable margarine contains only slight traces of vitamin. Even when margarine is mixed with a little milk, the content in vitamin A, as Halliburton and Drummond, and Drummond have shown, is quite inadequate.

Table II. and Fig. 2 show that the import of the raw materials for the vegetable margarine industry has increased enormously from 1909–16. During 1917–18 the import was insignificant, but increased again considerably during 1919 and 1920. If we compare the importation of vegetable fat with the consumption of milk fat, we find that the vitamin-containing milk fat is being replaced from year to year in increasing amounts by the vitamin-free vegetable fat, and this goes on progressively. Only the two years of the war—1917–18—make an exception, where the conditions were reversed and there also the obvious indication of the vitamin deficiency—the xerophthalmia—disappeared.

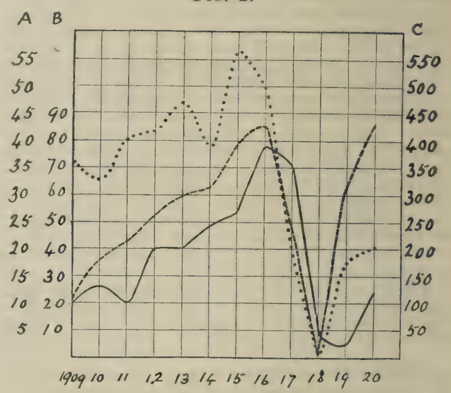
TABLE II.—*Proportion Between the Frequency of Xerophthalmia and the Import of Oil Cakes and Vegetable Fat.*

Year.	Oil cakes per cow.	Vegetable fat. Total imports.	Number of cases of xerophthalmia.	Year.	Oil cakes per cow.	Vegetable fat. Total imports.	Number of cases of xerophthalmia.
	kg.	mill. kg.			kg.	mill. kg.	
1909	367	10·4	20	1915	564	39·0	53
1910	329	17·4	26	1916	499	42·8	78
1911	403	20·8	20	1917	159	23·4	71
1912	419	25·7	40	1918	5	0·3	9
1913	479	29·7	40	1919	177	31·3	4
1914	391	30·7	48	1920	203	43·3	25

It must be taken into consideration that the vitamin content of the milk fat can vary too, and can thus influence the onset of xerophthalmia. Agriculture in Denmark is carried out according to modern principles. Stall-feeding or winter feeding has changed completely during the last few years. Formerly, the stall-feeding for cows consisted almost exclusively of hay and straw, while now one has gone over to turnips and oil cakes, which together with straw constitute the stall-feeding of cows. One knows that this feed is very poor in vitamin A, and one has been able to show that the vitamin-A content of butter and milk is considerably diminished as the result of this feeding. The table shows that the frequency of the xerophthalmia also follows the importation of oil cake. The extent of this importation is given in the second column of Table II.

This might possibly account for the fact that most of the cases of xerophthalmia occur during the months of January to May, while they are practically absent during June to December. During the first period the children receive milk fat which has been formed during the stall-feeding. During the second period green food constitutes a larger or smaller portion of the food of the cows. Blegvad has been able to show that in those years where the grass feeding begins soon the cases of xerophthalmia also disappear sooner in the summer.

FIG. 2.



- - - - - Import of vegetable fat in million kg. (Col. A).
▬▬▬ Cases of xerophthalmia (Col. B).
.... Oil cakes in kg. per cow and year (Col. C).

Xerophthalmia is Not the Only Result of Vitamin Deficiency in Denmark.

So far we have only dealt with the vitamin deficiency as it can be measured and studied clinically in man, taking as a criterion xerophthalmia. The results of animal experiments compel us to draw even more serious consequences. I have already mentioned that a diminution in the vitamin-A content of the food of the animals leads to xerophthalmia only in the most extreme cases. There is, in addition, the general effect: the diminished resistance against diseases, and the diminished vitality of the progeny.

Can a similar effect be demonstrated in Denmark?

The table of the consumption of milk fat shows that it was smallest during the years 1915 and 1916, and was greatest during the years 1917 and 1918, and partly also during 1919. We have, therefore, here an involuntary experiment on the importance of vitamins in which the whole population of Denmark was the test object. The harmful effects of the vitamin deficiency may be expected to manifest themselves by an increase in certain diseases during the years 1915–16, and as a late effect during 1917. Conversely, the increased consumption of vitamin A during 1917–18 and during the first half of 1919 should manifest its favourable effect by a diminution in the frequency of these diseases during 1918 and 1919.

In Table III. I have reproduced a preliminary extract from the statistical data on the causes of deaths in the town population of Denmark. I have there collected a number of diseases which are probably influenced by the deficiency in vitamin A. If we leave out the first three years we find that the infant mortality during the first year of life shows a great increase in the year 1916. It sinks in 1918 and reaches in 1919 the lowest value of the period. 1920 again shows a considerable increase. The year 1916 also shows the greatest mortality for children aged 1–5.

The vitality of the children is reflected in the number of cases in the column "Congenital debility." We see how the number of deaths from this cause gradually increases from 1914 to 1917 where the maximum for the period is reached; 1918 and 1919 show a diminution; 1920 again a considerable increase.

TABLE III.

Year.	Milk fat consumption in grammes per day and person.	Cases of death from—			
		All causes under 1 year of age.	Con-genital debility.	Rickets.	Tuber-culosis of the lungs.
1909	40·0	3136	696	32	1228
1910	35·6	3456	647	27	1190
1911	35·3	3191	653	34	1274
1912	32·3	2771	605	18	1331
1913	31·2	2830	673	20	1208
1914	30·4	2986	630	39	1267
1915	18·1	2625	694	27	1234
1916	15·3	3136	747	45	1492
1917	41·0	2835	771	24	1689
1918	51·5	2348	649	19	1307
1919	26·2	2549	608	23	1197
1920	18·9	3006	744	15	1204

It is well known that rickets is rarely a cause of death; rachitic children die, as a rule, from affections of the lung, and therefore these cases are usually entered in the column for lung diseases. The column for the mortality from rickets shows, however, that this reached its maximum in 1916. For adults, too, 1916 was a bad year. The mortality from tuberculosis of the lung showed for the town population during the years 1916 and 1917 a very considerable increase. Compared with 1914, the year 1917 shows an increase of over 30 per cent. After 1918 the mortality falls.

How to Deal with the Vitamin Deficiency.

It is clear that the conditions with which we have dealt represent a conflict between the economic and hygienic interests in Denmark. This has been revealed by the excellent work of Dr. Blegvad, and it is a problem which is not easy of solution. On the one hand, the great export of butter is bad for the health of the people; on the other, the economic well-being of the people depends on it. But vitamins and money go together. The well-to-do family can, by varying its food, provide itself with the necessary vitamins. They eat butter and drink milk: the less well-to-do people must be satisfied with substitutes poor in vitamins. Xerophthalmia occurs mainly amongst the poorer people. In view of this fact one can hardly expect that a diminution in the export of butter would be the solution. Perhaps the solution will have to be sought in making the cheaper substitutes for butter sufficiently rich in vitamins, but here, too, one meets with economic questions of considerable difficulty. The vitamin for the substitute must be cheaper than the vitamin of the milk fat if such a proceeding is to have any value. For the present, at any rate, the vitamin A of cod-liver oil is the cheapest. The amount of vitamin present in 350 tons (= 350,000 kg.) of cod-liver oil when consumed annually would certainly suffice to protect the whole population of Denmark against the dangers of a vitamin deficiency, and an importation of 600 tons would completely cover the vitamin export of the country.

How minute the amounts of the actual vitamin required are can be shown by the following calculation. The Norwegian pharmacologist, Poulsen, has prepared from cod-liver oil a substance which, when given daily in amounts of 0·004 mg. enables young rats to grow. An addition of 8 mg. per kilo. would be sufficient in order to give to margarine the vitamin content of butter, and a few bags of about 1200 kg. would be sufficient to contain the whole amount of vitamin exported from Denmark during one year. And still this preparation is by no means pure: perhaps its vitamin content is only a few per cent.

Clinical and Laboratory Notes.

TWO CASES OF SEMINAL VESICULITIS TREATED BY OPERATION.

BY HAROLD C. EDWARDS, M.B.LOND.,
HOUSE SURGEON, UROLOGICAL DEPARTMENT, KING'S COLLEGE HOSPITAL.

THE following are two recent cases of chronic seminal vesiculitis arising from infection of the urinary tract, and treated radically by a transvesical operation.

CASE 1.—The patient was a man aged 52 with a history of stricture. The first observation of urinary infection was made four years ago, when the patient had an attack of "influenza," and pus was discovered in the urine. The pyuria continued and the urine became thick at intervals. There was no disturbances of micturition. Last September the patient suffered an injury to the scrotum by falling across an iron fence. Dating from this time a swelling appeared in the left side of the scrotum which became larger and eventually burst, yielding a large quantity of pus.

Condition on Admission.—The patient was admitted to hospital on Nov. 24th, 1923. He had a discharging scrotal sinus. The prostate was normal in size and consistence. A large œdematous inflammatory mass occupied the position of the left seminal vesicle. The right vesicle was felt as a soft cushion. The patient suffered from periodic attacks of pyrexia, lasting usually 48 hours, with headache and profuse perspiration. The so-called "influenza" was probably an attack of this kind. The sinus in the scrotum was opened up and packed with iodoform gauze. A large quantity of pus was evacuated and the wound allowed to heal by granulation. Coliform organisms in pure culture were discovered in the pus.

The patient was discharged and readmitted on Jan. 22nd, 1924, when the radical operation described below was performed.

CASE 2.—The patient, aged 57, a very nervous type, had gonorrhœa 28 years ago, and had since had some difficulty in passing water. Two years ago he commenced to have periodical attacks of nocturnal incontinence, recurring at intervals of three weeks. On Feb. 22nd last year he had an attack of acute retention with strangury. The urine was thick. The acute condition subsided, but retention persisted, and the patient had to be catheterised twice daily. A few weeks later a suprapubic operation, in which a portion of the prostate was removed, was performed at another hospital. This partially relieved the obstruction but was insufficient, for the suprapubic wound did not close. It healed and broke down alternately for a period of nine months. The patient could not tolerate having a catheter tied in.

Condition on Admission.—The patient was admitted to hospital on Feb. 23rd, 1924. He had difficulty in micturition and a small stream. He passed water half-hourly in the daytime, but was incontinent while sleeping. The urea concentration was slightly subnormal (1·4 per cent.) and the blood-urea 37 mg. per 100 c.cm., without a urea meal—i.e., just within normal limits. The right lobe of the prostate was swollen and tender, and the right seminal vesicle formed a large film cylinder with a rough, uneven surface. The left lobe of the prostate was moderate in size, and the left seminal vesicle was not felt. The skin around the scar of the previous operation was red, œdematous, and tender, and urine leaked from a small sinus in the centre.

A New Technique.

In both cases the following transvesical radical operation was performed by Sir John Thomson-Walker. The technique of the operation varied only in detail.

The patient was catheterised and the bladder distended with normal saline. A mid-line subumbilical incision was made, and the bladder exposed and incised. The incision was extended and a bladder retractor put in position. An incision was made through the trigone and bladder base, extending from the posterior lip of the internal meatus to one and a half inches beyond the base of the trigone. This incision was continued round the internal meatus about a quarter of an inch from the orifice.

In Case 1 the seminal vesicles and the prostate were hard, indurated, and densely adherent. The vesicles and corresponding halves of the prostate were in turn dissected out with long rat-toothed forceps and curved scissors. A drainage-tube was stitched in the cavity left by removal of the vesicles and carried across the bladder to the suprapubic wound. A large drainage-tube was placed in the bladder, the anterior vesical wall closed by continuous suture, and the wound on the abdominal wall repaired. A catheter was tied in the urethra. The post-vesical drain was removed on the eighth day and the vesical tube on the ninth, together with the catheter. When the suprapubic wound was nearly healed a catheter was again tied in, and before removing the catheter it was plugged for an increasing period with a spigot. The patient was discharged from hospital on Feb. 26th, 35 days after the operation. The suprapubic wound was healed and normal micturition established. There was no residual urine. Pathological examination showed extensive inflammatory changes. No organism was cultivated from the vesicles.

In Case 2 the right vesicle was distended with pus. It was removed together with the prostate. The base of the bladder was closed by continuous catgut suture, and the postvesical area was not drained. Prevesical and vesical drains were inserted and the abdominal wound closed. A catheter was left in the urethra. The prevesical drain was removed on the fifth day and the vesical on the sixth, together with the catheter. A catheter was tied in while the suprapubic wound closed, and the bladder gradually distended. When the catheter was removed the patient passed water without difficulty. A No. 16 Lister's bougie was passed with ease. The patient was discharged 30 days after the operation. Pathological examination showed great increase of fibrous tissue and round-celled infiltration. The predominant organism cultivated from the pus was a coliform bacillus devoid of fermentative activity.

Comments on the Cases.

The common feature in these two cases was the presence of *B. coli* in pure culture as a cause of seminal vesiculitis. In the first case, the course was an abscess tracking to the surface and recurrent pyrexia from toxæmia, and, at the same time, symptoms of chronic cystitis. In the second case the symptoms were those of obstruction which had been mistaken for enlargement of the prostate. The transvesical method used by Sir John Thomson-Walker has the advantages over the perineal route that the approach is more direct; a full exposure is possible; there is no damage to the external sphincter (the compressor urethræ muscle) and therefore no danger of incontinence; there is no danger of urinary fistula, and none of damage to the rectum.

ON THE USE OF NON-INFLAMMABLE CELLULOSE SPLINTS WITHOUT PRELIMINARY PLASTER CASTS.

BY Z. P. FERNANDEZ, CH.B., M.D. LEEDS,
MEDICAL OFFICER, ARMLEY SANATORIUM, AND DEPUTY TUBERCULOSIS OFFICER, LEEDS.

THE decreasing mortality and crippling from bone and joint tuberculosis in children since the advent of conservative treatment with earlier diagnosis form a bright landmark in the oft-criticised tuberculosis campaign. In the case of adults there are many centres that still resort to the short cut by the knife, but the post-operative results in many of these cases are very disappointing, with return to work indefinitely put off.

I have published in THE LANCET [1] my experience of the fatal results of operated spinal cases admitted to our sanatorium. On the other hand, in spite of the adverse conditions of Leeds, our experience in following up adults treated on conservative lines with dispensary or domiciliary supervision has been very encouraging.

Rest is the key-note of the conservative method and splinting a natural corollary during the subacute or ambulatory period. Rollier condemns plaster splints for permanent use, but he freely employs celluloid splints in the ambulatory stage and in certain acute conditions. The disadvantages of plaster of Paris are well known. The preliminary plaster casts that are necessary in making celluloid splints and the time involved in drying led me to investigate a more easily applied substitute.

The use of cellulose acetate was suggested to me by the employment of cellulose dope or varnish for stiffening and weather-proofing aeroplane fabrics. I believe the dope has been used in artificial limb manufacture, but, as far as I am aware, not for splints. The cellulose acetate we use is quite different from celluloid, and is non-inflammable. We employ two solutions: Solution 26, which is thicker and more viscous, being used for the inner and outer coatings; and the thinner, solution 25, for the middle or additional coating. The finished splint has a glazed appearance, does not absorb moisture, and therefore well withstands perspiration.

Technique.

The part to be splinted is tightly covered with oil-silk or jaconette to prevent oozing and adhering of solution to the body. The different pieces may be stitched up and covered by an ordinarily worn under-garment, which may be made body-tight by a few stitches. Two or three Gigli's saw wires, 6 or 9 in. long, are then fixed by a coat of ordinary bandage in a straight line in a convenient anterior aspect. The ends of the saw wire must be left uncovered and loosely fixed to facilitate sawing out. About a pint or two of solution of cellulose acetate,[2] kept in a covered tin to prevent evaporation, and a good painting brush, 1½ in. wide, and ordinary bandages are got ready. It is advisable to work with gloved hands. For spine and lung splints a suspending posture is avoided by using the head and chin fixer made for me by Messrs. Reynolds and Branson. This permits lateral or vertical adjustment. If a standing posture is not possible the bandages are cut in pieces, and fixed by the cellulose solution. When dry, the patient is turned over, and the process completed. After a coat of the thicker solution is painted on to the layer of bandage fastening the saw (but avoiding the saw), two more layers of bandage followed by the cellulose thinner solution are put on. For the next three or four layers, crinoline or stiff material, such as used overalls, with a thick coat of cellulose will be sufficient. The splint may then be sawn out by an easy to-and-fro movement of the Gigli saw, having previously marked with ink the adjoining aspects of the splint to identify. The splint is removed from the body with the under-garment and oil-silk cut off by scissors. The two cut ends of the splint are stitched up at a few inches intervals, and three or four layers of bandage with three or four coatings of cellulose put on, ending with two final coats of thicker solution to give a glazed appearance. As a rule, the splint put on in the morning is ready to be cut out by the afternoon. For aeration the splint is perforated by a screw-driver. If expense is no concern, the edges may be leathered and hooks put on; otherwise braiding with thin pieces of bandage of the edges will answer the purpose, and strappings with buckles stitched on to fix the edges. A film preparation of cellulose acetate, known as "celastoid," will be found very convenient for the inner coat. This, cut in 4″ × 1′ size and warmed in tepid water, is easily moulded to the body-garment with the oil-silk and wire intervening. (Celastoid, with its high insulating property, could be of value in radiological work.) The next layers are completed with cellulose acetate on bandages. Though a little more expensive, celastoid gives a skin-like smoothness to the inner surface of the splint. The whole splint is made in a day at a very cheap cost, and is light, rigid, and pliable for adjustment.

These splints are of value in fractures and paralytic conditions, as they are conveniently put on without disturbing the patient. I hope that the technique I have followed will be of assistance to tuberculosis officers and to those interested in orthopædic work.

PS.—I have read with interest the paper in the last issue of THE LANCET on Surgical Tuberculosis in Egypt by Prof. R. V. Dolbey and Mr. A. W. Mooro. May I suggest that a trial of cellulose splints would overcome some of their difficulties regarding plaster application. It strikes me they are experiencing similar difficulties to those met with in this country years ago, when surgical cases were seen in an advancing condition without the help of a team of nurse visitors, propagandists, and preventive workers. With facility for heliotherapy in Egypt there seems no reason why conservative methods and earlier diagnosis should not gain the mastery there as they have done here.

---

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

AT a meeting of this section held on June 5th, Dr. CUTHBERT LOCKYER, the President, being in the chair, a series of three papers were read on the subject of

Wounds of the Gravid and Non-gravid Uterus,

being a study of uterine scars from the Gynæcological Department of the Glasgow Royal Infirmary.

Prof. J. MUNRO KERR dealt with the subject from the clinical standpoint, and started from the assumption that as the technique of gynæcological surgery gradually improved, it was necessary to realise increasingly the importance of conservative procedures in respect of the uterus. The operation of myomectomy was being gradually perfected, and most surgeons nowadays favoured conservative Cæsarean section in preference to sterilisation of the patient, all with the idea of conserving the uterus so that it could perpetuate its great function, and in order that in future pregnancies, should such occur, there would be no risk to either mother or child. Therefore, he contended, the profession could not rest content with an operation which gave 12 to 15 per cent. of mishaps in subsequent pregnancies. Myomectomy at the present time particularly concerned the gynæcologists, for two reasons. First, because the possibilities of the operation were not sufficiently appreciated, many performing hysterectomy when myomectomy was the more desirable operation. Many general surgeons who entered this region did not appreciate the extent of the conservative surgery which was possible. The second reason was that electrical and radiological experts with little knowledge of gynæcology carried out electrical treatment on these patients when such treatment was quite inadvisable. He ranged himself among those who contended that extensive myomectomies could be performed with gratifying results, and the operation should be developed and encouraged, in contrast with electrical treatment. He described the operation for resection of a uterus bicornis, which was done on one of his cases. The patient was aged 25, and when seen by him was two and a half months pregnant. As the cervix was dilated and the ovum could be felt through it, it was clear that it was not an extra-uterine pregnancy; but he could not decide whether it was a myoma complicating uterine pregnancy or a pregnancy in a double uterus. There was found to be a pregnancy in the right half. Later she had a second abortion in the right horn. He delivered a living child, but it died on the twelfth day of asphyxia following on the injuries at birth. Cæsarean section was done later, and a living and healthy child delivered, both returning home well. He did hysterectomy for her, as she dreaded another pregnancy. The scars were found to be good, and they consisted largely of fibrous tissue; they stood the strain of two pregnancies and two labours.

Prof. Kerr next described the case of a woman with a uterus having a rudimentary horn. Removal of the horn stopped the dysmenorrhœa, and some time afterwards she married and had an easy parturition. Since then she had had another labour, and that too was easy. He then described wounds in the uterus due to perforation of that organ with a sound. A specimen showed that very complete regeneration of muscle fibres might occur in a small wound of the uterus, but he did not think that was likely with a large wound in substance which was predominantly muscular; in such the scar would always be largely fibrous.

A fourth group of cases he dealt with were those in which Cæsarean section was done through the active contractile portion of the uterus. A number of such wounds were found to be defective and they gave way during subsequent pregnancy or labour. The scar seemed to be defective on its inner side, where there was a gutter. Infection of a wound was a most important factor in unsatisfactory unions, and another important factor was the material used for stitching the wound. Uterine muscle fibres during the puerperium were in a state of degeneration, and the sheaths of muscle forming the uterine wall were irregularly distributed and might not be exactly coapted. In conservative section the incision should be made over the lower uterine section, as this was less vascular than the upper and the surfaces of the wound could be more precisely approximated; moreover, it was more passive, and healing had a better chance. The mucous membrane should be separately stitched with very fine catgut or silk, and the edges of the fibro-muscular wall must be carefully coapted. He knew of no ruptures having subsequently occurred following this procedure, though the operation must have been performed thousands of times, especially in America and in Germany.

Dr. DONALD MCINTYRE showed by the epidiascope a large number of slides illustrative of his studies of various kinds of uterine scars, as well as a series of actual specimens. In a case of uterus unicornis there was shown to be fibrous thickening of the serous layer running into the myometrium, and in the deeper layer cicatricial tissue was present. In one case in which the ligature used was of silk minute strands of silk were found, surrounded by giant cells. The line of suture could be traced along an irregular course, and along this tract the fibrous tissue was increased in amount. Examination of scars after Cæsarean section showed that the muscle regeneration was perfect. When chromicised gut was used as the suture material there was no subsequent indication of the line of the suture. When unabsorbable material was used the ligatures might make their way to the exterior through the bladder, and the ligatures must cut through muscle before becoming free. In the majority of cases in which silk was used the knot remained intact. He had suggested to makers a combination of catgut and silk as a material for ligatures, and experiments had been made in three or four forms, specimens of which he showed at the meeting.

Dr. JAMES HENDRY dealt with observations made on the uterine scar after Cæsarean section: first, when the incision was made in the active contractile portion of the uterus; secondly, when it was made in the lower uterine segment. It was, he explained, a clinical supplement to the other two papers. At the second pregnancy after Cæsarean section he found no post-operative adhesions. The surface of the uterus might appear to be uniform, but to the finger passed over the surface depressions were evident, they could be felt rather than seen. In the first series—i.e., where the incision was made in the active contractile portion—the previous uterine wound could easily be traced, and there were a series of depressions, the inference drawn from this being that those areas were the seats of the original ligatures. Adhesions of a very dense type were present. In one case he did a classical Cæsarean section in August, 1921, and the uterine wound was closed with interrupted silk sutures. The abdominal wall healed by first intention, and the patient left the hospital on the twenty-third day. She returned three months ago stating that for six months she had felt what seemed like a knot in her womb, which swelled up when her periods occurred. He cut down and found a nodule the size of a green pea, but the scar appeared normal, as did the uterus. The nodule was excised and was found to consist of endometrial tissue encapsuled in white fibrous tissue. Another patient was readmitted complaining of urinary disturbance. A calculus was found with a silk ligature embedded in it; this was shown.

With regard to incision into the lower uterine segment, since May, 1921, he had carried this out in 41 cases. He incised transversely the loose peritoneum, and it was not necessary to disturb the bladder very much. The uterine wall was incised transversely. He now used two layers of continuous catgut for the uterine wall. In seven of the 41 cases the inner silk ligature was discharged per vaginam some time after the operation, and he had not experienced trouble from the ligatures in any other stage. The scar was indicated by a white line in two of the cases, and at the second operation that line was found to be free from adhesions. He set out in detail his reasons for choosing the incision in the lower uterine segment.

Discussion.

Dr. T. W. **EDEN** said the communications were of extraordinary interest, especially the portions dealing with the Cæsarean section scar. In days gone by Cæsarean section interested those of the specialty from the point of view of its indications, but that question had now been settled, and all that remained to be discussed in that relationship was the remote effect of incisions in the uterus. The way in which the operation had been popularised and was being done, not only by gynæcological experts but by surgeons and practitioners everywhere, rendered questions of technique as important as any surgical question existing at the present time. The amount of work which had been put into the subject by the three gentlemen who had read the papers was therefore of great value. Any degree of uterine sepsis during convalescence from Cæsarean section was a most important factor in the production of a weak scar afterwards. He had not regarded the material used for the ligaturing as a matter of great importance, and for many years he had been using only catgut; but he recognised that a great determinant of whether the uterine scar would be a sound one or not was the degree of sepsis present at the time. He asked whether one could ever expect a good uterine scar. That could only be settled by direct observation; but he had not understood why an end-to-end suture in the intestine, which was a contaminated structure, healed in a way which never caused weakening, while in the uterus it did not. The grave part of the communications had been that, even where there was an aseptic recovery, there might be a bad uterine scar. One reason was because the endometrial half of the wound was liable to heal badly, and a second reason was that the scar was liable to be invaded by endometrial tissue in a parasitic fashion, which produced another weak spot. Possibly the V-shaped depression in the inner half of the uterine scar might be got over by improvements in technique, but one could not control decidual tissue, and if it was likely to invade the scar and lodge into spaces it would be filled up by menstruation, and there would be a further weakening of the scar. Thus the gynæcologist was up against difficulties which he could not overcome. Perhaps the lower uterine segment operation would get rid of some of the difficulties, but he did not think it was altogether clear, from the histological points brought forward in the communications, that the lower uterine section scar would be perfect; there would be some risk of endometrial invasion, and even in that some irregularities of union had been shown.

Mr. **EARDLEY HOLLAND** said these contributions furthered the claims to superiority of the lower uterine section operation over the classical operation. From his experience of repeat operations he could say he had seldom, if ever, seen a perfect scar after a classical Cæsarean section. Constantly he saw scars which seemed perfect, but seldom were they free from one or several pits. With a finger in the uterus and one outside they could be palpated. He had done the lower uterine segment operation only 12 times, and he had found it a delightful operation in cases when the patient had been in labour, and not necessarily only when the labour had lasted some time, for it was so when the patient was no more than halfway through the second stage, as there was an appreciable development of the lower uterine segment. The operation was almost bloodless, one went through thin tissues which did not bleed, there was no need to hurry, and the fœtus was not jeopardised. It seemed as if one was extracting a fœtus through a fully dilated os. Performing the operation before the patient was in labour, however, had disadvantages. He made a curved incision with its convexity downwards, and a remarkably small incision was needed. He considered that the lower uterine segment incision had a great future, and that it would replace the ordinary classical Cæsarean section, at all events in the cases in which one expected the patient to have a repeat operation.

Dr. H. **RUSSELL ANDREWS** said the most alarming feature about the sections which had been shown was the depth to which the endometrium dipped in. The danger of having a weak scar was due to decidua getting into the layers of muscle. When there was more bleeding than usual in a case it was difficult to make sure of avoiding endometrium, and it was well to have more than one layer of sutures through the muscle. When once a patient had had a Cæsarean section, one felt one could not safely allow her again to have a labour in the ordinary way.

Prof. **MUNRO KERR**, Dr. **MCINTYRE**, and Dr. **HENDRY** replied briefly.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on June 4th, Sir **DAVID WALLACE**, the President, being in the chair, when Mr. J. W. **DOWDEN** read a paper on the principle of

Active Movement in Relation to Injury and Disease.

After briefly describing the anatomy and physiology of injury, Mr. Dowden said that a study of these subjects pointed to active exercise as the best remedy we had, not only for such conditions as fractures and sprains, but in many post-operative conditions. Amongst these he classed infected joints, infected tendon sheaths and cellulitis, and suppuration. Active movements were essential and should be commenced at once and carried out up to the point of producing pain. The patient must be encouraged daily to persevere in using his own muscles and his own brain. Passive movement and massage were not enough. It was his custom to commence active movements within 24 hours, and it was remarkable to see how the patient gained confidence and to what an extent the range of movement increased in a short time. By this means the tone of the muscles was kept up, adhesions were never allowed to form, and by the active contractions of the muscles the injured bones were gradually welded into shape and, in cases complicated by suppuration, the accumulating pus was driven from the wound. The paper was illustrated by many lantern slides which demonstrated in a remarkable way the healing processes in fractured bones after treatment by active movement. By following up cases for several years the speaker was able to show how perfect a functional result could be obtained, and he also had had the satisfaction of having X ray examinations which revealed no sign of previous injury in the bones.

Mr. C. W. **CATHCART**, congratulating Mr. Dowden on the success which had attended his work, said that great credit was due to him for the manner in which he had extended the work of Lucas-Championnière.

Mr. J. W. **STRUTHERS** said that while he had been much impressed by all that he had heard and seen of Mr. Dowden's work, he would have liked to have known more about Mr. Dowden's methods in the treatment of those difficult fractures which occurred now and then in the lower extremity. Most of the cases described were injuries of the arm in young persons.

Mr. **PIRIE WATSON**, Dr. D. **HUSKIE**, and Dr. J. W. **SOMERVILLE** joined in the discussion.

Dr. D. MURRAY LYON read a paper on the

Rôle of Dieting in Medicine.

By way of introduction Dr. Lyon briefly traced the history of dieting in medicine. Dieting was probably as old as medicine itself, for many diseases were accompanied by gastric upset which would call for a modification of food intake. Considerable progress was made along these lines by the empiricists, but the advent and application of organic chemistry and modern physiology had put the subject on a sound basis. Serious gaps still existed in our knowledge of many diseases, and dietetic systems based on faulty foundations had given rise to many fads and fancies. The primary objects in feeding were to supply heat and energy for the body and to allow for growth, storage, and replacement. When fats and carbohydrates were completely combusted in the body, they were said to yield exactly the same number of calories as they did when burnt up in the bomb calorimeter, but in the case of proteins combustion was not so complete, for the resulting end-products had still a heat value. Mellanby had suggested that too much attention had been directed to the calorie, and that other factors, such as the quantity and composition of the protein fraction, must be considered. The diet must include a minimum amount of protein containing certain amino-acids. Fats were of less importance, but the carbohydrate minimum was also fixed if acidosis was to be avoided. Other factors which must be present in the food were the various salts and bases and also the elusive vitamins. Dieting had proved of paramount importance in diabetes. Until recently the practice in treating diabetic patients had been to forbid the consumption of certain foods and to allow other articles of diet *ad libitum*, but a trial of Allen's principles taught us the enormous importance of regulating the diet. Insulin had further altered the outlook, for its use demanded the most careful dieting if hypoglycæmia was to be avoided. Dr. Lyon then proceeded to discuss some of the recent work done by Shaffer and Woodyatt, and pointed out its bearing in the construction of diabetic diets. The patient's glucose tolerance limited his intake of fat, and with regard to protein an amount equivalent to about 1 g. per kilo of body-weight was allowed. A fatty substance known as intarvin had recently been introduced which was almost equivalent in calories to an equal weight of butter, but, according to its discoverer, entirely harmless when taken *ad libitum*, since the organism could deal with it without the aid of carbohydrates and without giving rise to acid bodies. In nephritis considerable discussion had taken place regarding the diet. In the acute stages and in chronic cirrhotic lesions where nitrogenous retention was present it seemed desirable to limit the protein intake, but prolonged albuminuria meant a draining of protein from the system, and the practice of boldly raising the protein in the food had often given rise to apparently beneficial results. Where œdema was present attention to the salt content of the food was recommended, but in some cases restriction of the NaCl had no influence on the diet, and the author was tempted to ask whether any benefit could be derived from dieting such cases at all. Of the plans for treating peptic ulcer Dr. Lyon had had greatest success with the method put forward by Sippy. The principles here were to avoid those things which would call forth the gastric juice, to give small meals at frequent intervals and at the same time to secure for the patient sufficient calories. Under this régime pain ceased at once and within a few days a noticeable increase in weight took place. The science of dietetics was not only of interest to the physician, but was also of importance to the surgeon. Much could be done by dieting to put a patient into the best state for operation, and careful attention after surgical assistance would give the invalid the best chance of permanent recovery in the case of many gastric conditions.

Discussing the question of dieting in hospital practice, Dr. Lyon described what had been done by the institution in nearly all large American hospitals of a special class of official known as a dietitian. The position and duties of these people varied, but they were responsible for the preparation of the food, acting on the prescription of the physician in charge of the case, and by this means an unlimited number of cases requiring special diets could be handled without adding to the work of the ward staff. Another important duty of this official was to instruct those patients who required it in the best methods of constructing, preparing, and arranging their diets. From his experience at the diabetic out-patient clinic of the Royal Infirmary Dr. Lyon was convinced that the exact dieting required in this disease could be satisfactorily and readily carried out in general practice even by uneducated persons. Dieting played a part in preventive medicine, but the more the question was studied the more one was impressed with the multiplicity of causes which acted together in producing ill-health.

Dr. CHALMERS WATSON, in opening the discussion, said that it was necessary to give more attention to the bacterial flora of the intestinal tract before the influence of diet on the patient could be fully understood. He referred also to the great increase in the consumption of meat per head of the population in this country during the last 25 years.

Dr. CLAUDE KER said that from his experience of certain febrile conditions—for instance, typhoid fever—he was tempted to agree with Dr. Lyon and ask if diet in these cases had any beneficial effects at all. Typhoid cases seemed to do equally well on a full diet, on a light diet, or even on practically no diet. He was interested to hear more of the rôle of the dietitian, and now that such an office had been established in the Royal Infirmary he felt sure that it would not be long before a special dietetic kitchen was built, which would be of great help in the handling of those cases which required special care.

Dr. HUSKIE believed that in the construction of diets it was essential to consider the personal idiosyncrasies of the patient.

Prof. G. M. ROBERTSON, Dr. SOMERVILLE, and Dr. C. G. LAMBIE also took part in the discussion.

Mr. PIRIE WATSON exhibited and described a specimen of bilateral hydronephrosis due to blockage of each pelvis by a single calculus.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.—This association will meet in conference in London from July 14th to 19th. The association was inaugurated in New York in 1919, and held a meeting in Geneva in 1922, at which the constitution was drawn up. It is expected that some 24 nations will be represented at this London meeting, the first to be held under the fully constituted representative council. There will be business meetings, and a discussion on Maternal Morbidity, its Causes and Prevention, and there is a full and varied programme of entertainments and expeditions. The hon. secretary of the Hospitality Committee is Dr. Kathleen F. Lander, 49, Albany-street, N.W. 1, from whom all particulars may be obtained.

ENCEPHALITIS LETHARGICA IN NORTHERN IRELAND.
A considerable epidemic of encephalitis lethargica has prevailed in Belfast and the surrounding area during the last few weeks. Up to June 6th the number of cases notified in Belfast was 198, with 16 deaths. The attacks, our correspondent writes, have varied much in intensity, some being very mild, others severe. The initial stages have been characterised in some cases by severe neuralgic pains in various parts of the body and choreiform movements, which have given rise to some difficulty in diagnosis. Marked mental perturbation has been common. A mild and irregular pyrexia has been the rule. Double vision has been a frequent symptom, and paralyses of some of the cranial nerves have occurred in many cases. The stuporous condition seems to have been less marked than in the last visitation in 1921, and some patients have had a prolonged period of extreme restlessness, requiring restraint. The disease has not spread in households, and there has been hardly any definite evidence of direct infection. The cases have occurred sporadically in various parts of the city, and neither age nor social position seems to have much, if any, influence. It is too soon yet to draw any conclusion as to the prospects of complete recovery. Many cases have run a protracted course.

Reviews and Notices of Books.

CARDIOLOGY.

Modern Methods in the Diagnosis and Treatment of Heart Disease. By Francis Heatherley, M.B., B.S. Lond., F.R.C.S., Temp. Capt. R.A.M.C., Superintendent Heart Clinic, Manchester; and Cardiologist to the Ministry of Pensions. London: Baillière, Tindall and Cox. 1923. Pp. 199. 5*s.*

This volume of 200 pages was written at the suggestion of a colleague with whom the author was associated while acting as cardiologist to the Ministry of Pensions at Manchester. The work was undertaken with the object of presenting to the general practitioner a sketch of our present-day knowledge of heart disease. It is not intended as a text-book, and is only a general outline of the common disorders of the cardiovascular system, without reference to the special and well-known methods of instrumental examination. The book has been submitted to Sir Thomas Lewis and Dr. John Hay for their criticism and it is apparent that much of the information given in this small volume comes from the published works of these well-known authorities.

In the opening chapters the author contrasts the modern conception of heart disease with the older views. There is a chapter on the arrhythmias, which should be helpful to the general practitioner who has had no experience with polygraphic and electrocardiographic methods. There is a good description of heart failure with congestion; in dealing with heart failure of the anginal type the teaching of Mackenzie has been followed. Pain, breathlessness, palpitation, giddiness, and other symptoms of myocardial exhaustion are briefly considered in the light of recent investigations, and the physical signs of structural disease of the heart are treated in a similar manner. A short chapter on prognosis and treatment includes a helpful account of the procedure to be employed in getting the patient with auricular fibrillation under the influence of digitalis.

This book can be recommended to practitioners, as showing the methods which the medical officers of the Ministry of Pensions have employed with great success in dealing with cardiovascular disease.

The Heart. By Dr. Selian Neuhof, B.S., M.D., Visiting Physician, Central and Neurological Hospital; Consulting Cardiologist, Broad-street Hospital, New York. London: Stanley Phillips; Philadelphia: P. Blakiston's Son and Co. 1923. Pp. 701. $10.00.

The aim of the author in publishing this book is to present the entire subject of cardiac and cardiovascular disturbances and diseases in a clear, well-balanced manner from the clinician's rather than from a highly specialised viewpoint. He has succeeded in this aim, for his book covers the entire field of cardiovascular disease, functional and structural, in an admirable manner. He has written a book of 700 pages in readable English, well illustrated, with many diagrams, tracings, and electrocardiographic curves, and an inclusive bibliography.

The book is divided into two parts, the first, of 33 chapters, covers the whole field of cardiovascular disease. The opening chapters deal with the embryology and anatomy of the heart, the fœtal circulation, and congenital malformations in the usual text-book manner. In an early chapter there is an adequate discussion of our present-day knowledge of the physiology of heart muscle. Cardiac histology and pathology are briefly treated with two good paragraphs on hypertrophy. In summing up our knowledge of the dynamics of a normal heart cycle and its clinical application to cardiac dilatation, the author is of the opinion that such dilatation unless extreme is not easily recognised, and that we should use the term cardiac dilatation with great caution. Many pages are given to graphic methods; he explains the use of the Mackenzie polygraph, and how radial and venous tracings should be analysed. The principles of electrocardiography, the use of the Einthoven string galvanometer, and the interpretation of curves, are described in a manner suitable for a text-book of this nature. All the essential information upon the arrhythmias is contained in three chapters of 80 pages, each type of irregularity being illustrated by many polygraphic tracings and electrocardiographic curves. In the chapter dealing with the X ray examination of the heart, orthodiascopic standards are accepted as representing accurately the size of the heart. Telerontgenography gives excellent results, but lacks many of the advantages of orthodiascopy for clinical purposes. There is a very good description of the physical signs associated with cardiac enlargement and valve disease. In the discussion of systolic murmurs the statement is made that organic murmurs are easily distinguished from non-organic murmurs. This view is not generally accepted. In the chapter on heart failure, the symptoms and signs associated with it, the functional tests for estimating cardiac reserve, are well dealt with. In his description of the clinical features of subacute infective endocarditis, the author fails to mention clubbed fingers as a valuable sign of this disease. Cardiac syphilis is treated in the usual text-book style, and the remaining chapters conclude a comprehensive outline of cardiovascular disease which should be helpful to both student and general practitioner.

Part II. consists of a series of cardiovascular clinics in the form of case-histories given as a course of clinical conferences to senior students of medicine. The volume is well bound and printed on good paper, with not more than the usual number of typographical errors.

Der Einfluss tiefer Atmung auf den Herzrythmus und seine klinische Verwendung. By the late Dr. Alfred Pongs, Privatdoz. f. innere Medizin, und Oberarzt d. med. Universitäts-Klinik zu Frankfurt a/M. Berlin: Julius Springer. 1923. With 160 tracings. Pp. 326.

The well-known sinus-arrhythmia is dealt with at some length from a theoretical and experimental point of view, and the alterations in the heart-rhythm in both general and heart disease are exemplified by the description of numerous cases under the author's care. There is, unfortunately, no index; but the book should appeal to the clinician no less than to the cardiologist.

A Key to the Electrocardiogram. By Louis Faugeres Bishop, M.A., M.D., Sc.D., F.A.C.P., Professor of the Heart and Circulatory Diseases, Fordham University, U.S.A., School of Medicine, New York City. London: Baillière, Tindall and Cox. 1923. Pp. 96. 15*s.*

These 15 chapters are an expansion of papers read at different times before specialists and general practitioners. It is doubtful whether a reader without knowledge of electrocardiography will find the book helpful in understanding the mechanism of the heart-beat, or useful in distinguishing normal from abnormal electrocardiographic curves. To illustrate the exactness of electrocardiography in the clinical examination of the heart as compared with auscultation, the author, in the preface, compares the movements of a frog in a closed box as determined by listening to the sounds made by the animal, with watching the movements of strings attached to its legs. This is typical of the style in which this book of 96 pages is written. In his efforts to explain the irregularities of the heart and other signs revealed by the electrocardiograph, the author in discursive style employs similes and metaphors which are sometimes useful but sometimes untimely. In attempting to explain in simple terms the principles of electrocardiography, he fails to give a true impression of the real value of the galvanometer in the clinical examination of the patient with cardiovascular disease. In the appendix there is a photograph of the Hindle electrocardiograph, and directions are given for the installation of an electrocardiograph, and the procedure usually adopted in taking an electrocardiographic curve. In this country the galvanometer in general use is the instrument made by the Cambridge and Paul Instrument Co. Directions given for the Hindle will not apply to the Cambridge and Paul instrument.

MICROBIOLOGICAL TECHNIQUE.

Handbuch der mikrobiologischen Technik. Edited by Prof. R. KRAUS (Vienna) and Prof. P. UHLENHUTH (Freiburg, i/B). Berlin: Urban und Schwarzenberg. 1924. Vol. III. Pp. 987. Swiss Fr.41.25; bound, Swiss Fr.45.75.

THE third volume of this handbook contains a number of chapters of interest. The late Prof. A. Klöcker, of Copenhagen, deals with the cultivation of yeasts. This chapter is followed by a well-illustrated one on pathogenic fungi for which Prof. H. O. Plaut, of Hamburg, is responsible. Insects of pathological importance are dealt with in chapters by Dr. A. Lutz, of Rio de Janeiro, and Dr. R. Haas, of Berlin, respectively; the latter also describes methods for breeding and handling them. Chapters follow on pathogenic worms, on filarias, on soil organisms, on the microbiological investigation of milk, of water, and of air. A brief chapter by Dr. T. Péterfi gives an account of the new subject of micro-dissection, here called the "micrurgical method," which has been developed and practised until now almost exclusively in America. The most interesting chapters are those by Prof. W. Rosenthal, of Göttingen, on the technique of filtration and ultra-filtration with special reference to the isolation and demonstration of the filterable viruses. These two chapters give a very complete account of the whole subject and contain a remarkably extensive bibliography of nearly 700 references. A number of chapters on the organisation and equipment of bacteriological institutes complete the volume—a somewhat unnecessary addition to a very bulky tome.

The work contains much information which is not readily found in the ordinary text-book and should prove a useful book of reference.

MODERN THEORIES OF THE UNCONSCIOUS.

By W. L. NORTHRIDGE, M.A., Ph.D. With an Introduction by Prof. J. LAIRD, M.A. London: Kegan Paul. 1924. Pp. 194. 8*s.* 6*d.*

Dr. Northridge gives an account of early theories of the unconscious as propounded by philosophers, and shows their relation to and contrast with modern theories, which, he says, have been built up out of a close study of mental data and, for the most part, with a practical aim. The views of these philosophers are given with a scarcity of dates which is unkind to the tyro. One can, for example, only discover by close reading that Hartmann's "Philosophy of the Unconscious," in spite of its apparently up-to-date title, belongs to the period between Schopenhauer and William James. One of the few dates provided is, however, of interest. Thomas Reid wrote that "every operation of our mind is attended with consciousness, . . . and to speak of perceptions of which we are not conscious is to speak without any meaning." This reads like a fragment of current controversy, but was written in 1785. W. H. Myers is taken as the first exponent of modern ideas, though his introduction of a "supernal faculty" made his "subliminal self" a confusion of two conceptions. The development of theory is traced in the work of Janet, Morton Prince, and others, and a critical and historical account is given of Freud's psycho-analytical practice and theory. The author dismisses Jung's "collective unconscious" as unnecessary, and agrees with Rivers in denying that repressed sexual tendencies are always the real cause of a neurosis. To justify this conclusion he quotes the result of an analysis which lasted only six sittings and removed the symptoms after the abreaction of experiences which the patient had "largely succeeded in banishing from her mind." Psycho-analysts would certainly reply that no true analysis took place.

Dr. Northridge struggles with the difficulty of conceiving unconscious mental processes which possess all the attributes of conscious ones except that the subject is not aware of them, and finds it too great. Writing in no carping spirit, he declares that "There cannot be 'unconscious ideas' or 'unconscious wishes' unless what introspection reveals to us of our conscious processes is hopelessly astray." This sums up the position perhaps better than the author realises, and accords with other passages in which he shows his reluctance to give up a belief in the unchallenged supremacy of the consciousness. Unlike other objectors to the theory of the unconscious, he has found it to be true that those who pour scorn upon psycho-analysis will understand its value if they put it to the test themselves. His own tentative formula for the content of the unconscious is unsatisfying, and it seems that for those who share his difficulty the only escape is to accept the current theory with the proviso that some things happen as if it were true, but other things contradict it.

The historical part of the book should lead psycho-analysts to look with respect upon pre-analytical philosophers. Dr. Northridge's practical contributions are too slight to be of value in themselves, but there is so much a priori denial of psycho-analytical findings that one welcomes the advent of a critic who has put the principles to the test of practical investigation.

TOPOGRAPHICAL ANATOMY OF THE HEAD AND NECK OF THE HORSE.

By O. CHARNOCK BRADLEY, M.D., D.Sc., M.R.C.V.S., Principal, Royal (Dick) Veterinary College, Edinburgh; Lecturer on Comparative Anatomy, University of Edinburgh. Edinburgh: W. Green and Sons, Ltd. 1923. With 96 illustrations. Pp. 228. 21*s.*

THE present volume forms the last of three by the same author dealing with the topographical anatomy of the horse, the limbs and trunk having already been considered. The aim of the work is the same as that of its admirable companion volumes—viz., to act without over-elaboration as a dissection guide. Its appeal is therefore directly to the student, and although the head and neck are not of same daily importance to the practitioners as the limbs and trunk, it should also be of value and interest to him. Over 40 out of a total of 214 pages are devoted to the brain, spinal cord, and their coverings. The directions, descriptions, and illustrations are of the same high standard as in the earlier volumes. There are good tables and a full index. An ambiguous statement appears in the first sentence on p. 180, where under cerebral nerves the author states: "Twelve pairs of nerves arise from each half of the brain." This surely must be double the actual number. The work will undoubtedly be used in those veterinary schools where modern nomenclature is taught.

AIDS TO PRACTICAL PATHOLOGY.

By F. W. GRIFFIN, M.A., M.D., B.C. Camb., Assistant Pathologist; and W. F. M. THOMPSON, Chief Technical Assistant, Virol Pathological Research Laboratories. London: Baillière, Tindall and Cox. 1923. Pp. 246. 4*s.*

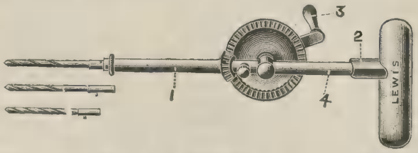
IN this volume the authors have faced the formidable task of bringing together for the use, not only of students and practitioners, but also of laboratory workers, the great bulk of the procedures more commonly used in bacteriological, histological, and biochemical investigations. Notwithstanding the fact that the book contains only 246 pages, being of the compact and handy format of all its predecessors in the "Aids" series, there is hardly any well-recognised procedure of laboratory diagnosis that fails to find place therein. The descriptions of the technique of the various methods are clear and to the point. The wholly inexperienced might find it difficult to work from the book alone, but most of the descriptions are such that any given method, or a kindred one, having once been performed under supervision, it should be possible for a worker of reasonable intelligence to carry on by the book.

It is a reflection of the spirit of the medicine of the day that most of the bacteriological technique is compressed into the first 45 pages; the bulk of the remainder of the book is devoted to biochemistry, the methods of morbid histology coming in for a scant 18 pages at the end. The whole is severely practical; as a cram-book it might well be productive of "brain fever," but as a bench manual, both for the present-day medical student and the laboratory worker, it will be of real value. Some references are given; more would have added to the value of the book.

New Inventions.

AN IMPROVED BONE DRILL.

I wish to bring to the notice of your readers an improved bone drill (see figure) which I have had made to my design. Its object is to avoid the faults of the ordinary bone drill—namely, (1) defective balance; (2) insufficient length; (3) uncomfortable handle; and (4) a gear-wheel handle which does not revolve freely on its axis. In the improved bone drill (1) the instrument balances at the spot marked 4 in the figure, and as a consequence seems almost to retain itself at right angles to the bone automatically without any muscular effort on the part of the surgeon, and without any tendency for the drill-point to snap off in the bone; (2) the stem which holds the detachable drill-point has been doubled in length, marked 1, enabling the drill to be used in the deepest wound without the surgeon's hand coming anywhere near it; (3) the tiring of the fingers, in consequence of the unsuitable shape of the part of the stem which meets the handle at right angles, is obviated by making this part of the stem marked 2 flattened from above downward; (4) the handle revolves freely on its long axis, but has no projecting milled head or screw of any kind, and one can turn it for any length of time without the glove becoming caught and damaged with the consequent spoiling of aseptic technique. Briefly, the merits of the instrument are that it balances itself without any conscious effort on the part of the operator: there is no fear of the drill-point snapping off, the drill can be used without the hand of the operator entering the wound, and without his glove getting torn. Any number of holes can be drilled without causing the slightest fatigue or discomfort.



Messrs. Lewis and Sons, 2, Westmoreland-street, London, W. 1, are the makers.

Paul Bernard Roth,
Orthopædic Surgeon to the Miller General and Homœopathic Hospitals.

Reports and Analytical Records.

FRIARY NON-DEPOSIT DINNER ALE AND FRIARY DOUBLE STOUT.

(Friary, Holroyd and Healy's Breweries, Ltd., Guildford.)

These two samples of bottled beers have been submitted to us for examination. When analysed the following results were obtained:—

	Dinner ale.		Double stout.
Specific gravity of wort before fermentation	1038·15°	..	1039·68°
Present specific gravity	1011·94°	..	1013·02°
Alcohol per cent. by volume ..	3·4	..	3·5
Extractives per cent. (total soluble matter)	4·3	..	4·6
Acidity per cent. as acetic acid ..	0·07	..	0·08
Original wort solids fermented, per cent.	56	..	55
Fermentable sugar still present, per cent.	0·75	..	0·83
Preservatives (salicylates and sulphites)	Absent.	..	Absent.

Both beers were in good condition, brilliant and entirely free from deposit. They were extremely palatable, and have clearly been brewed from high-class materials on sound lines. The pleasing appearance of the ale and stout in glass and the attractive and novel get-up of the bottles indicate that the proprietors of this well-known brewery appreciate the æsthetic aspect of marketing our national beverage.

"BILINA": NATURAL DIGESTIVE WATER.

(The International Development Co., Ltd., 4, Trafalgar-square, W.C. 2.)

This water is derived from springs situated close ot the town of Bilina in Czecho-Slovakia. When analysed it was found to have the composition (expressed as grains per gallon):—

Chlorine (Cl)	11·87
Sulphuric acid (SO_3)	35·05
Lime (CaO)	12·15
Magnesia (MgO)	4·54
Silica (SiO_2)	2·80
Soda (Na_2O)	135·04
Potassium and lithium	Traces.
Specific gravity (water = 1000)	1004·46

These are probably combined as follows:—

Sodium chloride (NaCl)	19·58
,, sulphate (Na_2SO_4)	62·15
,, bicarbonate ($NaHCO_3$)	264·4
Magnesium bicarbonate ($Mg(HCO_3)_2$) ..	16·5
Bicarbonate of lime ($Ca(HCO_3)_2$)	35·1
Silica (SiO_2)	2·8
	400·53

This is a somewhat remarkable water of the Vichy type, and the bulk of the saline constituents are in the form of bicarbonates. The water is well charged with carbonic acid gas, and it possesses the agreeable salty taste characteristic of bicarbonate of soda. The sodium sulphate present confers on it slightly laxative properties.

ENERGEN BREAD.

We have received the following communication from the Therapeutic Foods Co., Willesden, London, N.W.:—

"In the report published under the above heading in The Lancet of May 24th we notice the observation 'that the manufacturer should state the percentage of carbohydrate in his product, since this practice would be of great assistance to the physician in prescribing a diet.' We are entirely in agreement with this view. This Company has always issued to the medical profession complete analyses of all the Energen products, and these are at the disposal of any physician who may be good enough to apply to us for them."

THE LANCET.

LONDON: SATURDAY, JUNE 14, 1924.

EPIDEMIC DISEASE IN THE FAR EAST.

As an outcome of a proposal put forward by Dr. Miyajima, the first Japanese representative on the League of Nations Health Committee, to that Committee, a mission was despatched at the end of 1922 to the Far East to collect information in regard to the incidence of epidemics in important ports where international complications might be expected and where measures were necessary to prevent the transmission of these diseases to other centres. The original proposal was to form a mission of three or four public health experts of high standing in their different countries, but Dr. Norman White undertook the inquiry single-handed, as it was found difficult in the time available to nominate other authorities who could be spared from their posts for as long a period as six months. Dr. Miyajima accompanied the mission throughout the visits to Formosa, Korea, and South Manchuria; and in the part of the tour which covered Hong-Kong, Shanghai, and Japan, Dr. H. F. Smith, of the Public Health Service of the United States, also acted as an unofficial and valuable colleague, but the resulting report of the mission must be looked upon as practically individual.

The scope of the inquiry was large, as befitted so fundamental an idea. It was proposed to include in the report not only the ascertainable facts on the incidence of the most important epidemic diseases in the various ports of the Far East over a period of five years, and to note the part played by shipping in the spread of infection and the efficacy of quarantine regulations, but also to discover the possibility of diffusing useful information upon epidemic outbreaks and endemic pestilences among the constituent nations, to provide a scheme for the interchange of experiences, and to frame some form of convention for regulating national and international efforts along the indicated lines, securing especially uniform procedure in the chief ports in respect of public health and quarantine regulations. In many ways the report meets this large reference satisfactorily. The total distance covered in Dr. Norman White's itinerary was 35,000 miles, exclusive of short journeys of inspection, and the whole of this extensive journeying was accomplished between Nov. 28th, 1922, when he left Bangkok, and July 29th, 1923, when he arrived at Marseilles, some of the principal places visited being Singapore, Java, Hong-Kong, Shanghai, Tokyo, Peking, Saigon, Rangoon, Calcutta, Bombay, and Marseilles. The stay in certain of the ports was necessarily of a limited duration, but in spite of the rapidity of travel and the brevity of the visits an enormous amount of information was collected. This has been compared, amplified, and verified by Dr. White in his report with all the health publications and monographs necessary to complete the various sections of the work; while the investigations on the spot are described in greater or less detail as the facts have warranted, neither formal questionnaire was issued nor was special pattern of inquiry followed. The early chapters deal with plague, cholera, and small-pox in the Far East, plague being given precedence as, all things considered, the most important ship-borne disease in the Orient. The chapter on plague condenses with clearness the more salient epidemiological facts emerging from a study of a history of the disease during 25 years, and among the points on which Dr. White insists are the evidence for considering bubonic plague and pneumonic plague to be two distinct diseases, and the conclusion that the plague bacillus alone cannot cause widespread epidemics of pneumonic plague. Stress is laid on the non-infectiousness of human bubonic plague; this is another way of saying that as an epidemiological problem we are dealing with a rat disease first and last, so that, if it were possible to break the association of rats and grain, the control of the disease might be assured—at any rate, as a ship-borne scourge. The monograph on cholera indicates upon statistical grounds that certain provinces in British India are by far the largest and most persistent centres of cholera infection in the world. Here, says the report, the cholera problem is one of unparalleled difficulty, being bound up with considerations of centuries-old customs, habits, and prejudices, but the attention at last being given to rural sanitation in India should work a vast improvement. The question of small-pox in the Far East is dismissed briefly, though the existence at different dates of serious and widespread epidemics is noted. The view held in the report is that, though the infection is more widespread than with plague or with cholera, the dangers of transferring infection by ship are confined almost entirely to such classes of passengers as labour squads or pilgrims, while the general attention paid to vaccination in all parts of the East minimises these dangers.

There follows an elaborate draft for a sanitary convention between the countries concerned for the control of infectious diseases in the Far East, based upon the results of the mission, to which is appended a Bill of Health form which would be a most desirable one for use in all ports in the Far East where, at the present time, Bills of Health are frequently of little or no value, their object in certain places appearing even to be the express withholding of information. The plan for this convention, as proposed by Dr. White, is not on all fours with the existing International Sanitary Convention of 1912. Some parts of it, indeed, may prove difficult to reconcile with the principles on which the official revision of that Convention is now proceeding. But the draft has the obvious advantage of indicating to governments the kind of problems which may have to be met by some future form of international agreement. The concluding and greater portion of a voluminous and admirable document is occupied by series of detailed facts in respect of the incidence of all epidemic diseases in the special centres visited, with a plea for an international epidemiological intelligence bureau for the Far East. The monographs as they concern various localities are based upon assistance freely offered from many authoritative sources, and Dr. White here, as elsewhere in his report, points out the great help he has received in his work from different quarters where he has found personal acknowledgment impossible, and where he has had no opportunity of submitting the resulting sections to revision by collaborators. All these chapters prove the practical utility that such an intelligence bureau would have, for combinations to delimit epidemics can only be set in motion in response to prompt and precise knowledge. The important functions of the proposed bureau would be to summarise in a convenient form, and to circulate to all signatory countries and to the health organisation of the League of Nations, matters of public health and statistical urgency. To this bureau each country would state what it considered necessary with regard to ships arriving from an infected country; it would detail the facilities which would be granted on arrival and the measures which would be enforced before departure. The director of the bureau would be in a position to correspond with the port administrative officers, and to these functions others, as they became indicated by experience, might be added. The suggestion to establish such a bureau is in accord with the expressed views of many authorities, and it seems probable that it will be placed before the League of Nations Council at their forthcoming meeting, when Singapore is obviously indicated as the place for such a central station.

◆

A PROBLEM OF NUTRITION.

The second decade of this century has witnessed a unique experiment in nutrition, in which a whole nation was the test object. The results of this experiment, which was an involuntary one and proceeded in Denmark, are of far-reaching importance. We owe our knowledge of the matter to two Danish physicians, Dr. C. E. Bloch and Dr. O Blegvad. Dr. Bloch[1] observed in 1917 an outbreak of keratomalacia in a children's institution. He could show that the children, although living on a mixed diet, did not receive a sufficient supply of the fat-soluble vitamin A in their diet owing to the fact that the main supplies of this vitamin in a child's dietary, butter and whole milk, had been replaced by margarine and skimmed milk. Dr. Blegvad collected all the cases of xerophthalmia and keratomalacia which had occurred throughout the country during the 12 years 1909–1920. He investigated carefully the conditions under which the disease developed, the age of the children, their food, their general state of health, the economic position of the parents, the seasonal incidence of the disease, and so on, and published this material last year in Danish in a monograph entitled "Om Xerophthalmien." Quite recently he has published a summary of his work in English in the *American Journal of Ophthalmology*. To-day we publish a paper by Prof. E. Widmark, of Lund, Sweden, who, on the basis of Dr. Blegvad's work, draws conclusions of great general importance. We learn from Dr. Blegvad's interesting historical account of the disease that it was first defined as a clinical entity about the middle of the nineteenth century by Arlt and a few years later by von Gräfe. The ætiology of the disease was so little understood that until the beginning of this century the mortality in infants developing keratomalacia was almost 100 per cent., so that the onset of the disease was regarded as a symptom of imminent death. In 1903 Fehr noted as a curiosity a case of keratomalacia in a baby whom he succeeded in saving from death. And as late as 1913 a publication based on 93 cases gave a mortality of 50 per cent.

The discovery of vitamins has revolutionised the outlook on this disease. It has been possible to reproduce the disease experimentally in animals by keeping them on a diet poor in the fat-soluble vitamin A and to cure it again rapidly by administering food substances rich in this vitamin, such as cod-liver oil or butter fat. Incidentally Dr. Blegvad makes an interesting contribution to the history of medicine by showing that the treatment of night-blindness—an early symptom frequently associated with xerosis conjunctivæ and occurring in badly nourished children—is mentioned in Eber's papyrus, dating probably from 1500 B.C. The treatment recommended by the ancient Egyptians was the administration of liver, and we know now that of all animal tissues the liver of herbivorous animals and of many fishes is particularly rich in the fat-soluble vitamin. This knowledge seems to have spread from Egypt all over the world. For Hippocrates recommends raw ox-liver dipped in honey, and in Japan and China the liver of hens and of sheep were used. This treatment with ox-liver persisted even to the beginning of this century. Dr. Blegvad's theory is based on 453 cases of keratomalacia, of which all but 19 occurred in children, and 148 cases of xerosis of the conjunctiva without keratomalacia. From a careful consideration of all the factors involved Dr. Blegvad concludes that the main ætiological factor of the disease in children is the same as in young animals—namely, a diet poor in the fat-soluble vitamin A. In terms of ordinary foodstuffs the disease in Denmark, at any rate, is due to the substitution of margarine for butter and of skimmed milk for whole milk. All the cases in which the weight of the children were recorded showed a greatly impaired growth. The disease might be called an economic disease. It occurred only among the children of the poorer classes. The treatment consisted in giving whole milk with or without cod-liver oil. In Bloch's cases, which could be treated in an institution, and where, therefore, the diagnosis could be made at an early stage of the disease, the mortality was thus reduced to 10 per cent. The mortality of the cases collected by Dr. Blegvad was still 21 per cent., mainly owing to the fact that the disease begins so insidiously that the children were not brought to the doctor soon enough. It is a significant fact that the cause of death was nearly always broncho-pneumonia—another striking similarity to the condition observed in animals, which die usually from septic lung conditions. Although the disease itself yields so effectively, vision usually remains damaged. Only 14 per cent. of Dr. Blegvad's cases recovered with undamaged vision, 27 per cent. were blind, and 24 per cent. had vision greatly reduced in both eyes, while in 35 per cent. visual acuity was reduced in one eye.

It would be a mistake to look upon Dr. Blegvad's work merely as a striking illustration of the solution of a clinical problem by the data furnished by experiments on animals, with a corresponding reduction in the mortality from 100 per cent. to nearly 10 per cent. Its significance goes much further. The experience of Denmark has demonstrated beyond doubt that the teachings of the new physiology of nutrition, associated with the conception of vitamins, cannot be neglected with impunity by a community, even though it may live under the conditions of our civilisation on a varied and freely chosen diet restricted only by economic considerations. The widespread belief that since we live on a mixed diet we somehow pick up enough of the necessary vitamins to maintain us in good health is shown to be mistaken. And the extent of the vitamin deficiency must not be gathered from the relatively few cases of the eye disease which have been observed. This is merely a final symptom when the deficiency has reached the extreme stage. It is associated with other disturbances such as malnutrition, anæmia, general debility, diminished resistance to respiratory infections, which make their appearance long before the eye disease develops. As Prof. Widmark puts it, for every case of xerophthalmia there is a whole army of patients whose health has been undermined by deprivation of vitamins, but whose diseases get other names. The same view has recently been expressed by Dr. W. Cramer [2] in a lecture published in our columns. He emphasised the necessity of an *abundant* supply of vitamin for the maintenance of health especially in a young organism. He pointed out that one of the results of our present civilisation has been to deprive those foodstuffs, which are the main supplies of vitamins, of their vitamin content, and he gave reasons for believing that this may constitute a serious danger to the health of a nation. The data collected in Denmark and presented by Prof. Widmark can leave little doubt as to the reality of this danger. We have a vast amount of ill-health among the children of this country. Sir George Newman, in his report on the health of the school child, states that while 80–90 per cent. of the children are born healthy, 35–40 per cent. of the children who are admitted to school at 5 years of age bear with them physical defects which could have been either prevented or cured. He does not exaggerate when he describes this as the most serious and wasteful defect in our national health service, and he attributes this appalling result mainly to bad housing, parental neglect, and absence of hygienic supervision, and these are no doubt important factors. But the complete omission of an adequate supply of vitamins as one of the causes of this vast amount of preventable ill-health is striking, though the importance of this factor is as yet little appreciated in this country. Good housing, care, and cleanliness cannot make up for a deficiency in this factor, for the disease xerophthalmia has occurred in institutions where, in spite of repeated investigations, no fault could be found with the conditions of life of the children until the discovery of vitamins gave the clue. The problem of an adequate vitamin supply to the community, which affects the health of the nation so closely, is a vast one; it involves not only medical and biochemical considerations, but is also an economic and a social problem. It well deserves the labours of a Special Committee.

SEX DETERMINATION.

Sex is determined by the sex chromosomes, two in number. In females these are similar to one another, and are generally denoted X and X; in the male they are dissimilar, morphologically and functionally, and are marked X and Y. In the reducing divisions leading to the formation of eggs and spermatozoa these numbers are halved. As a result all eggs have one X chromosome, some spermatozoa have an X, some spermatozoa have a Y. By random fertilisation between eggs and spermatozoa so constituted a population is produced of individuals with XX (which are females) and individuals with XY (which are males) in approximately equal proportions. The sex chromosomes contain genetic factors other than those determining sex, and the qualities determined by these factors are therefore inherited in relation to sex—for example, hæmophilia.

Such in its simplest form is the explanation of sex puzzles which modern histological and experimental work have combined to elaborate into a singularly convincing whole. The whole question is dealt with in a most interesting and comprehensive way by Mr. Julian Huxley in *Medical Science* (1924, x., 91), and we are glad that the Medical Research Council takes the wide view which enables the readers of its journal to familiarise themselves so conveniently with the present state of knowledge in a subject which has advanced with bewildering rapidity and has almost endless medical implications. Take, for example, the sex-ratio and the possibility of varying the ratio and even of influencing the sex of a particular child. At birth there are about 103 males to 100 females; it is known that fœtal mortality falls more heavily on males, and the primary ratio—i.e., the ratio at the time of conception—is probably about 120 or even higher. Hence, since X and Y spermatozoa are produced in equal numbers, the Y variety must have some advantage. It has been shown that human spermatozoa are of two sizes, and since the Y chromosome is smaller than the X the ones with the smaller heads may reasonably be assumed to be genetically Y or male-determining. It is not difficult to imagine that herein lies the advantage which the Y spermatozoa have, that they are more easily able to burrow about and make their comparatively long journey from the vagina to the Fallopian tubes. And lively eugenic imaginations will see in some method of differential filtering or diffusion a means of getting a boy or girl at will. Profuse copulation is also known to have a considerable influence on the ratio, Hays' experiments on rabbits bearing out the "vulgar error" that moderation is more likely to result in boys. Artificial selection of inbred stocks may also lead to brands of rats with familial tendencies to ratios as different as 122 and 82. But though maleness has an advantage at the outset, the balance is severely against it afterwards, and, as is well known, the excess mortality among male children reduces the ratio to less than 100 after the first few years of life. The most likely explanation of this is that in the sex chromosomes are carried also recessive factors which, when they become manifest by appropriate matings, are lethal or tend to lethality: such a character is more likely to appear in males with one X chromosome than in females, in which both must be simultaneously affected to produce the result. Or consider the exhibition of sex in secondary sexual characters. Each cell in the body of a female is different in its chromosomes from each cell of a male. But this does not directly lead to differentiation of the secondary characters. Once primary sex is determined, secondary development is brought about by hormones from the gonads, and by alterations in these hormones the fundamental chromosome constitution of the body can be overridden. Hence the effect of castration and the occurrence of sex reversal. The chromosomal mechanism on which this and much more depends is mechanically delicate, and, as may well be imagined, does not always effect its complicated manœuvres with complete precision. Mistakes occur and lead to various pathological results. Similar errors in the other, non-sex, chromosomes may well account for many of the individuals which do not fit the world and come to untimely deaths of one kind and another. Some of these relatively or absolutely non-viable products are also the inevitable result of particular matings of heterozygous individuals, so constituted that some recessive character, in the parents unrecognised and harmless, comes to the front. The thoughtful hygienist will find in Mr. Huxley's summary much food for reflection on nature and nurture and the lines along which hygiene must look for progress.

From a more general point of view, one of the most interesting facts brought out is that the arrangements outlined do not hold throughout the animal series. Thus in mammals and diptera—e.g., the famous *Drosophila*—the male has two dissimilar chromosomes, while in birds and moths it is the female that is the heterogametic sex, and the eggs are of two kinds rather than the spermatozoa. In insects, too, the secondary sexual characters, often extremely prominent, are due to the different constitution of the cells which form them, and are not influenced by the gonads: castration with or without implantation of a sex-gland from the opposite sex makes no difference. We have here another illustration of the great biological truth that the end and not the means is the determining factor. The end in this particular case is the production of males and females in something like equal numbers: the means by which this is attained is not always the same, any more than the means by which reproduction and maintenance of the species is always achieved by the sexual process.

Annotations.

"Ne quid nimis."

CONCERTED CARE OF CRIPPLES.

AT the present time there are about 100,000 crippled children in this country, of whom it is believed that 90 per cent. need not have become cripples had the knowledge we already possess been put to practical use. A business-like scheme of attack was started in the county of Salop in the year 1900, and from this beginning has grown a large work all over the country organised by a central committee, of which Sir Robert Jones is chairman and Dr. F. Barry Lambert hon. secretary. This committee works in close touch with the Invalid Children's Aid Association under a joint board whose chairman is Mr. H. S. Souttar, F.R.C.S. We have just received a report of this Central Committee for the Care of Cripples (Carnegie House, 117, Piccadilly, W. 1), covering the two years 1922–23, which shows steady progress in the organising of the care of cripples in many different localities. In Shropshire the work is so far advanced that the orthopædic hospital no longer has a waiting list, and from Oxfordshire comes the cheering news that comparatively few new cases of long standing are now being discovered. There are 125 beds at the Wingfield Orthopædic Hospital, Headington, Oxford, as well as three small wards for private cases and clinics scattered over the three adjacent counties—namely, Chipping Norton, Witney, Henley, and Banbury in Oxford; Wallingford, Sandhurst, Wantage, Wokingham, and Newbury in Berks; Aylesbury, High Wycombe, and Newport Pagnell in Bucks. It is the experience of the Central Committee that wherever a clinic sets to work there is a constant and increasing flow of cripples as a result, the expectation being three cripple children per 1000 of population. Nowhere else is the work so well organised as in the two counties named, but elsewhere good beginnings are recorded. Two after-care orthopædic clinics have been opened in Cheshire, one at Chester and the other at Crewe; 257 cases were sent within the year from the adjacent counties to the Ethel Hedley Hospital at Calgarth Park, Windermere, where they were visited by surgeons from Manchester. In Essex the Walthamstow U.D.C. has provided free of rent and rates for a year the orthopædic hospital at Brookfield, served by the neighbouring public authorities. During the last two years a clinic has been opened at Hereford, and five orthopædic centres in Hertfordshire (St. Albans, Hertford, Hitchin, Letchworth, and Watford) where the massage clinics originally started for the treatment of ex-Service men are being retained by the county nursing association for orthopædic work. The Central Hospital at Longfields, Stoke-on-Trent, provides 40 beds for the North Staffordshire Cripples' Aid Society. A Red Cross Curative Post at Woking is under the surgical supervision of orthopædic surgeons from St. Thomas's Hospital. In Wiltshire a clinic is being started at Devizes and the open-air ward at Bath has already been noted in our columns. The joint committee of the two cognate associations has made it its aim to provide a clearing house for all cases sent out of orthopædic hospitals with no obvious provision for after-care. There is pressing need for new schools in the country for these children; the cripple has to learn in school hours many things which the normal child learns unconsciously, and in addition he must get a sound vocational training, when he has an 80 per cent. chance of becoming a self-supporting citizen. Unfortunately, in spite of conference with makers it has been found impracticable to standardise splints and instruments so as to reduce their cost by increased production. The ambition of the Central Committee is not to allow any preventable deformity to occur, and work on these lines is making great strides.

ELEPHANTS AND ETHNOLOGISTS.[1]

AN ethnological note, in the form of a well-illustrated quarto volume, has just been published by Prof. Elliot Smith, which, while full of learning and thoroughly documented, has the joyousness of a breezy quarrel. After all, ethnology is a very human subject, and it is very human to enjoy a quarrel. The points at issue may be briefly stated as follows. There are elephants and there have always been elephants in India, and their representation is a frequent feature of decorative sculpture in South and South-Eastern Asia. There are no elephants in America; at any rate, geology produces no evidence of their existence since primeval times. Yet in Honduras, among an imposing collection of ruins, a stela, or decorated pillar, exists adorned with animals which can hardly fail to be recognised as elephants, and bearing also the huge face of a Mongolian. Without dogmatising as to the date of this stela, it is inconceivable that sculpture upon it should have derived any decorative details from some memory of an American primeval beast. How, then, can the ornamentation on the Copan stela, in Honduras, be explained? And why does it need explaining?

The need for explanation arises from the fact that it is a dogma with a certain school of ethnologists that the civilisation which existed in America before the days of Columbus had its origin in the West, and derived nothing from Asia. Identities in primitive customs and nomenclature are justified by the theory that, it being natural for steps in human development to occur along certain lines, there must have been two developments occurring separately, one for the West and one for the East. Things may have been so, but with equal certainty they may not have been so. Why the principle of separate development should be an article of almost religious faith with one class of thinkers is not clear, but from the contents of this book we must assume that to hold a contrary view—as we happen to do ourselves—is an act of impiety. The champions of what may be called the all-America-out-of-America school argue that the ornaments on the Copan stela are not elephants at all but parrots or tapirs, or the result of pure imagination, evolved from the inner consciousness of the ancient artists.

No reply is attempted to those who think that the ornaments are the outcome of mental evolution, and those who would explain the elephants by some accidental similarity between sculptural flourishes and an animal with a trunk are also not to be argued with. No doubt the beliefs are honest, though their basis is frail. The pictures in the book appear to show distinctly the head of an elephant with, in one case, a turbaned *mahout*. The explanation which allows that the carving is intended to be an animal of some sort, and suggests that it is a tapir, does not explain the presence upon it of a turbaned *mahout*. Another explanation is that, scale being admittedly of no consequence, the decoration is a representation of a sort of parrot, the blue macaw, and this interpretation appears to be arrived at by mistaking the inconspicuous eye of the elephant for a nostril, and its ear for an eye. Looked at in this way the sculpture certainly has some resemblance to the profile of a beaked bird, but it must be remembered that there are four beasts on the stela, of which only one, and that the most damaged one, lends itself to the theory. What is the impossibility that the beasts, being elephants, should have been sculptured by persons who, though they had never seen elephants themselves, had seen representations of them, with their *mahouts*? Small articles so adorned could find their way to Honduras from India and China by the medium of adventurous Melanesians and Polynesians. This would explain everything, and requires no violent assumption, for it is known that some of the natives made long and adventurous voyages, pushing East, step by step, from island to island, while there is much evidence that the Polynesians had ways and means of reaching America which were employed some centuries before the discovery made by Columbus. What is the absurdity of this theory that should tempt those who disagree with it to be rude about it ?

---

[1] Elephants and Ethnologists. By Prof. G. Elliot Smith. Woodcuts by A. H. Gerrard and K. Leigh-Pemberton. London: Kegan Paul. Pp. 136. 15*s*.

We recommend this book to all who, while valuing the lessons of ethnology, are not aware of the extreme pains necessary to comprehend the ancient messages. Prof. Elliot Smith produces a mass of evidence in support of the view that the influences of Asia might be found in the remains of the pre-Columbian civilisations of America, and Mr. Gerrard and Mr. Leigh-Pemberton have coöperated in a series of remarkable woodcuts. The testimony cannot be pushed aside as supporting " an extravagant hypothesis, long since relegated to the rubbish pile of scientific discords." Such an attitude towards scientific opponents is not to be commended.

ACTION OF TESTICLE ON OVARIAN GRAFTS.

Drs. A. Lipschütz and H. E. Voss have carried out some interesting experiments, described in the *Comptes rendus de la Soc. de Biologie*, in order to throw light on the mechanism of the inhibitory action exercised by the testicle on experimental glandular hermaphroditism. It has previously been shown that if ovarian grafts are made in an intact male guinea-pig no enlargement of the breasts occurs, the effect of the grafts being inhibited by the action of the testes. Lipschütz and Voss have, however, now found that if previous to the grafting the lower pole of the epididymis be removed so as to convert the testicles into fragments having no connexion with their excretory ducts, the inhibiting action of the testicles is prevented, with the result that the ovarian transplantation produces a marked development of the breasts. This at first sight would suggest that the inhibiting action exerted by the testicles on the ovarian grafts depends on spermatogenesis rather than on the interstitial cells. The experiments, therefore, as far as they go, are in harmony with the view that is held by many investigators, that the hormonal function of the testes is not entirely centred in the interstitial cells. The epididymectomy carried out by Lipschütz and Voss is similar in its effect on spermatogenesis to ligature of the vas. It must, however, always be borne in mind that regression in the tubules does not occur immediately after ligature or epididymectomy, but only after an interval has occurred. Intact tubules, as Mr. Kenneth Walker pointed out in an article published in THE LANCET of Feb. 2nd, are found in the human subject as long as three months after vasotomy. Care must, therefore, be exercised in interpreting Lipschütz's experiments as a proof that the inhibitory action exercised by the testicle on an ovarian graft is entirely dependent on the existence of spermatogenesis.

SCHISTOSOMIASIS.

THE scattered literature on the subject of the schistosomiasis of the Far East, the disease produced by the trematode, *Schistosoma japonicum*, has been collected and coördinated by Drs. E. C. Faust and H. E. Meleney in the Monographic Series of the *American Journal of Hygiene* (No. 3, March, 1924), where they have supplemented and embellished our knowledge of the fascinating subject with a considerable amount of original work. This monograph consists of some 339 pages with a comprehensive index, and is abundantly illustrated with drawings and microphotographs. There is included an appreciation of the historical aspect of the schistosomiasis problems which was badly needed, and in this survey the fine work of the earlier Japanese investigators is given due credit. Other sections deal with the morphology, biology, and life-history of *S. japonicum*, its development with the molluscan host, the cercaria stage of the fluke, its development within the definite host—all the stages being well depicted by means of accurate comparative outline drawings and photographs. The migration of the fluke in the human body, the pathological anatomy of the disease, the clinical and therapeutical aspects are all passed under review, while the portions dealing with the biology of the intermediate hosts, the geographical distribution of the disease, and the question of its efficient prophylaxis are all welcome. The monograph contains two important appendices. The first, a zoological study of the molluscan hosts of *S. japonicum*, is from the pen of the late Dr. Nelson Annandale, F.R.S. elect, and must have been completed shortly before his death. Emanating from such a source, and from the zoological survey of India and the Indian Museum, Calcutta, this contribution is quite authoritative. The accurate description of the snails is illustrated with some fine illustrations of their morphology, and from this it appears that the correct nomenclature of the intermediate hosts is *Oncomelania*, Gredler (1881), of which there are three species—*nosophora*, *formosana*, and *hupensis*—which act as intermediaries in various parts of the Far East. The genus *Blanfordia* is now known to be quite distinct. The other appendix contains a full bibliography historically arranged.

GOITRE IN BRITISH COLUMBIA.

GOITRE affecting animals in British Columbia has a seasonal incidence, being more prevalent in late winter and early spring when the fresh green food of summer is not available. An article by Dr. W. D. Keith, of Vancouver, in the April issue of the *Canadian Medical Association Journal*, draws this and other interesting conclusions from his own personal observations. The incidence of goitre in the valley which he studied has disappeared entirely following on the use of iodine. Sanitation appears to play little part, for in the Indian Reserve, where conditions seem most favourable for spread of contagion, no goitre was found either among live-stock or human beings. But goitre was endemic in the Pemberton Meadows, inhabited only by white men during the last 30 or 40 years on a virgin soil with remarkably pure water-supply. Certainly, the iodine-deficiency theory of goitre is strongly supported by the evidence which Dr. Keith brings forward. There may be other factors. In a recent British Medical Association lecture [1] Dr. R. McCarrison still lays special stress on one of these—namely, the continued infection of the bowel by way of polluted water. But wherever goitre arises in the absence of bowel hygiene, Colonel McCarrison would now assume insufficiency of intake of iodine in food and water. The method of prevention of goitre by iodine, he states, is at once simple, rational, cheap, and devoid of ill consequences.

THE ULTIMATE RESULTS OF RADICAL OPERATIONS FOR MIDDLE-EAR DISEASE.

IT is a disappointing feature of radical operations for middle-ear disease that they so often leave a serous or purulent discharge which, though it may not be a serious danger, is, at any rate, a blemish and a social hindrance. The causes of this sequel are various ; it may be that the operation has not been radical enough, some of the diseased bone having been left behind, or, as happens frequently, the operator has not succeeded in providing the cavum tympani with an epithelial lining suited to its modified functions. Yet another important cause of a persistent discharge is neglect of after-care, of that periodic supervision which patients should enjoy for at least a year after a radical operation. It is this lesson in particular that Dr. P. Henius and Dr. H. I. Schousboe emphasise in the last number of *Acta Oto-Laryngologica* (1924, vi., fasc. 1 and 2). In the autumn of 1922 they investigated the fate of the 301 patients on whom a radical operation for middle-ear disease had been performed in the period 1901–20 in a Danish hospital. In 19 of these cases the operation was performed on both sides, and in 65 cases cholesteatomata were found. Of the 13 patients who died in hospital, as many as 12 showed intracranial complications before the operation. Among the 288 patients who left hospital alive, there were 234 about whom information was obtained in 1922. Eleven were found to have died, but in no case was the cause of death connected with the operation. Of the 135 patients who submitted to a re-examination in hospital, 15 had been operated on for middle-ear disease on both sides. There were thus 150 operation results to check, and only in 67, or 45 per cent., was the operation wound found to have healed completely. Among the remaining 83 cases of imperfect healing, a mucous discharge from the Eustachian tube or from the imperfectly healed cavum tympani was the most common defect. In other cases there was a comparatively profuse and often purulent discharge from the cavum tympani or other parts of the field of operation where granulation tissue and, at a few points, denuded bone were found. Some of the worst cases, from the point of view of healing, were also the worst cases from the point of view of elementary cleanliness on the part of patients whose indifference and inertia were mainly responsible for the accumulation of wax and epithelial debris. In many cases a short course of after-treatment effected complete healing of the operation wound, and the authors insist that it would be well if every patient undergoing a radical operation for middle-ear disease were to be instructed to report periodically, say once or twice a year, for supervision, and, if necessary, a short course of after-treatment.

---

[1] Brit. Med. Jour., June 7th, p. 989.

A JOURNAL OF INFECTIOUS DISEASES.

Prof. R. Kraus, of Vienna, is editing a new journal, with the title of *Seuchenbekämpfung*,[1] which has as its object to keep the general practitioner and veterinary surgeon in contact with recent developments of experimental medicine, especially in its application to infectious diseases, such as vaccine therapy, chemotherapy, protein therapy, and new methods of prophylaxis. The literature on this subject is so vast, so difficult to appreciate critically by the non-expert, frequently so contradictory, that the general practitioner may well be excused if he lets his innate conservatism get the better of him. The aim is to present positive achievements which are ripe for application in general practice in the form of brief and clearly written articles by authorities of standing. The first number opens with an article of ten pages by Dr. J. Gerstmann, on the Malarial Treatment of General Paralysis. Details of the treatment are given and the conclusion is reached that "the dogma of the incurability of this disease has been overthrown." This is followed by a paper from Prof. Pirquet's clinic, on the present state of diphtheria prophylaxis. Prof. Przibram has a paper on the diagnosis and ætiological treatment of bacillary dysentery. Prof. Kraus writes in favour of the curative and prophylactic value of anti-tetanus serum. Other papers in this number deal with the technique of the production of antitoxic sera, the technique of collecting specimens for bacteriological and serological examination, the experimental production of cancer by tar, the animal epidemics in Jugoslavia, and the methods employed in fighting them. The last paper is a short note by Prof. Kraus dealing with certain ill-effects encountered in immunising sheep against anthrax. The papers are clearly written, and if the standard set by this first number can be maintained the journal will certainly be a useful addition to current medical literature. It was apparently conceived by Prof. Richard Paltauf, whose death, recently recorded by our Vienna correspondent, removes one of the last surviving pioneers of bacteriology and serology. His labours, which were devoted particularly to the application of bacteriological discoveries and methods to practical medicine, have gained for him a distinguished place in one of the most remarkable periods in the history of medicine.

AN OVERCROWDED MENTAL HOSPITAL.

THE impression that certifiable mental disorder in Ireland is increasing is confirmed by the annual report (for 1922) of the Ballinasloe Mental Hospital, which has just reached us. Here the number of patients increased in the course of the year by 49 to a total of nearly 1500, although the medical staff consists of three members only. The inspector's report opens with the sentence, "This mental hospital is greatly overcrowded." Apparently the dormitories being full of beds, corridors are also being used as sleeping apartments. This report contains other serious criticisms; food and clothing were of bad quality, the grounds were not well kept; "the attendants' rooms were not in a proper state of order and cleanliness"; the women's exercise grounds were entirely inadequate; more patients could have been usefully employed, some of those who were working had been hired out to farmers, "a practice objectionable on more than one ground." Two suicides and two fatal and many non-fatal accidents are recorded; various infectious diseases, including typhoid, have been prevalent; the deaths from tuberculosis numbered 14. No mention is made of therapeutics. It is to be feared that the bad conditions reflected in this report are only too common in Irish asylums, and are due directly or indirectly to financial difficulties. The efforts of the staff might be expected to produce certain improvements, but initiative may well be discouraged by the impoverished aspect of the inadequate buildings in which they work.

RAT-BITE FEVER.

Dr. Paul A. O'Leary,[1] associate in the Section on Dermatology and Syphilology of the Mayo Clinic, states that since rat-bite fever was first described by Millot-Carpentier in 1884 about 140 cases have been recorded. The disease has occurred in all parts of the world, but is naturally most prevalent in those countries where rats are numerous, such as Japan, England, France, and the United States. In 1915 Futaki described, under the name of *Spirochæta morsus muris*, an organism which he had recovered from rats and from patients suffering from rat-bite fever, and therefore regarded as the cause of the disease. Hitherto, however, only Japanese observers have succeeded in isolating this organism in cases of rat-bite fever in man, and other organisms have been regarded as of ætiological importance, such as a streptothrix, by Tileston, Schottmüller and Blake, a sporozoön by Ogata, and a diplococcus by Douglas, Colebrook, and Fleming.[2] Dr. O'Leary, who records two illustrative cases, pays special attention to the dermatological manifestations of the disease, which he classifies under the headings of roseola, indurated erythematous plaques, lesions of the mucous membranes, and alopecia. The roseola consists of large reddish-blue or purple macules scattered diffusely over the lower extremities, neck, and face, in contrast with the roseola of syphilis which is more pronounced on the trunk. The macular lesions usually appear with the first attack of fever and rapidly undergo involution, leaving brown pigmented patches which may remain for several weeks, but do not usually persist throughout the disease. The most characteristic lesion of rat-bite fever is the indurated bluish-red or livid plaque with a lighter coloured concentric zone just within the margin. The lesions are widely disseminated and vary in size. The larger plaques are, as a rule, definitely indurated, and may be surrounded by smaller non-indurated macules. With each exacerbation of fever the older or fading lesions become more distinct, and new lesions may appear, subsiding in their turn with the fall of temperature. Œdema of the skin is sometimes a prominent feature, its extent depending on the situation of the indurated lesions. Coarse, flaky desquamation follows the involution of the erythematous plaques. The skin lesions become less numerous and distinct as the disease progresses, and disappear altogether as it subsides spontaneously or is arrested by intravenous injection of neo-arsphenamin, as occurred in one of Dr. O'Leary's cases.

DR. EDMUND SMITH'S RETIREMENT.

HIS colleagues in the public health service will have learned with regret of the impending retirement through ill-health of Dr. Edmund Smith, medical officer of health for the city of York. Dr. Smith was York's first whole-time medical officer, and the quarter of a century during which he has held office has been a time of great progress in public health matters. During his first year there was an extensive epidemic of typhoid fever in York, which led to the gradual abolition of the conservancy system and the improvement of the sewers. Voluntary notification of pulmonary tuberculosis was adopted at an early date, and a complete scheme for dealing with tuberculosis has since been built up. An excellent maternity and child welfare scheme has come into being as the result of whole-hearted coöperation with the York Infants' Welfare Association. In his report for 1922 Dr. Smith told of the opening of the new maternity hospital at Acomb Hall, a building admirably adapted for the purpose with accommodation for some 40 patients. One of the principal features of public health work in York has been the happy blending of municipal and voluntary effort, in no small degree due to the tact and enthusiasm of the medical officer of health. Comparison between the death-rates in the year of Dr. Smith's appointment (1900) and the last year for which figures are available (1923) shows that the general death-rate has fallen from 20·3 to 10·3; the tuberculosis death-rate from 2·10 to 0·86; the infant mortality-rate from 211 to 51. We are not surprised to learn that the cause of Dr. Smith's retirement has aroused deep sympathy on the part of the citizens whom he has served so faithfully.

WE regret that by an oversight the name of Surgeon Rear-Admiral Charles Marsh Beadnell was omitted from the list of Birthday Honours in our issue of June 7th. Admiral Beadnell received the C.B., Military Division.

THE annual dinner of the Federation of Medical and Allied Services on June 20th will be held in the Crown Room at the Connaught Rooms, Great Queen-street, W.C. This alteration of place has now become necessary owing to the applications for tickets having greatly exceeded the accommodation available at the Langham Hotel.

Dr. Arthur Hurst will deliver the Savill (Memorial) Lecture at the house of the Royal Society of Medicine, 1, Wimpole-street, W., on Thursday, July 3rd, at 5 P.M. Dr. Hurst has chosen Migraine as his subject, and the chair will be taken by Sir William Hale-White, President of the Royal Society of Medicine. These lectures were founded in connexion with the West End Hospital for Nervous Diseases. Any member of the medical profession will be admitted on presentation of his card.

AT a meeting of the Board of Governors of the McGill University, Montreal, on Thursday, June 5th, it was announced that the sum of half a million dollars had been granted by the Rockefeller Foundation to the Medical Faculty of the University for the establishment of a university medical clinic in coöperation with the Royal Victoria Hospital. We also learn that Dr. J. C. Meakins, Christison professor of therapeutics at the University of Edinburgh, has been appointed director of the clinic.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXV.

TREATMENT OF ACUTE GONORRHŒA IN THE MALE.*

GONORRHŒA in the male has an incubation period of 3–21 days; the average is 5, any time after 10 is rare. The earliest symptom is a slight gumminess of the meatus, associated with a sense of chafing. This appears usually on the second day after contact, and, if a smear is then taken, gonococci are present. This is an important fact not generally known, most practitioners waiting until pus shows on the third to fifth day. The inflammation at this stage is still confined to the squamous epithelium of the fossa navicularis, where the gonococcus can lead only a precarious life. It has not yet spread to the columnar epithelium of the urethra proper, where the organism can speedily burrow between the cells, invade the racemose glands of Littré, and establish itself firmly. The importance of recognising the gonococcus thus early, and before pus formation, is due to the fact that at this stage it is still possible occasionally to abort an attack.

Abortive Treatment.

The most successful method is that of Ballenger. After the patient has urinated, the glans and meatus are cleaned with spirit, and 20 minims of 1 per cent. protargol, or 1/2000 collosol silver, is instilled into the anterior urethra with an ordinary hypodermic syringe. The lips of the meatus are then closed, and sealed with a strand of cotton-wool soaked in collodion flexile. The penis is then held erect until the seal has dried. After three hours this seal is removed with acetone, the patient meanwhile having been instructed to drink 1½ litres of Contrexéville or barley water. The same manœuvres are repeated six hours later, and, if pus formation has not started, continued on the two succeeding days. The method probably acts by increasing osmosis. Its success can scarcely be due to the strength of the gonococcicide used. In private practice a small proportion of first-attack cases can be aborted in this way, and it is therefore worth the attempt, particularly in married patients. In hospital cases it seldom succeeds. Carelessly used it aggravates the attack, especially in relapse cases. The points to remember are: (1) Not to use more than 20 minims—the normal capacity of the urethra. (2) Not to use silver nitrate, as is often done—it is a dangerous drug to seal up. (3) Never to attempt the method if pus is actually present—damming up the discharge in this way only aggravates the condition.

Treatment of an Established Case.

When definite pus develops, the patient should be given a saline purge, and the bowels regulated throughout the attack. This appreciably diminishes the chance of posterior spread. A suspensory bandage should be worn, and the penis carried in a bag containing medicated cotton-wool to catch the discharge. Riding, cycling, dancing should be interdicted, all alcohol prohibited, spicy foods and coffee deleted from the diet. Urinary antiseptics are of no value in the acute stage of the disease. Sod. bicarb., gr. xx. quartis horis, to reduce acidity, may be required if micturition is painful. Bromides by the mouth and suppositories of atropine, gr. 1/75, should be prescribed if painful erections occur.

The purulent discharge is attacked in three ways: (1) by chemotherapy, (2) by vaccines, (3) by irrigations.

---

* An article in this series on Acute Gonorrhœa in the Female will appear in the next issue of THE LANCET.

Chemotherapy.—Here the drug *par excellence* is manganese butyrate. It should be given by intramuscular injection into the buttocks on the first and fifth day of the discharge, in doses of 1·0 c.cm. and 1·5 c.cm. of a 1 per cent. solution. Extremely gratifying results follow its use, the acute stage of the disease being materially lessened. Only two injections should be given—a third aggravates the condition.

Vaccines.—These are of great value in the acute stage of the disease, and in my experience clinical evidence is overwhelmingly in favour of vaccines of the non-toxic variety. The Lock Hospital vaccine is prepared in a strength of ten thousand million to the c.cm. It can be given every five days. The initial dose is 0·25 c.cm., increasing to 0·5, 0·75, 1·0 c.cm., and continuing at 1·0 c.cm. whilst required. A negative phase does not appear to be produced, and complications such as epididymitis are rarely seen if this form of therapy is used.

Irrigation.—This plays an important, but subsidiary, part in the treatment of the disease. If the urethra were a simple tube without glands it would be an easy matter to devise some wash-out method which would speedily cure the condition. Unfortunately Nature does not work in this way, and, by the time the discharge is in evidence, the gonococcus has already penetrated below the surface of the mucous membrane, invaded the glands of Littré, and entrenched itself well beyond the reach of any antiseptic that the urethra will tolerate in a strength sufficient to penetrate. Failure to recognise this fact, and persistence in using irrigation to the point of irritation, is responsible for many of the prolonged cases of urethral discharge which are so common in every clinic to-day. Irrigation should be used mainly for the mechanical purpose of washing out accumulations of pus. It is the increase in antibodies produced by the natural reaction of the body, and augmented by the use of vaccines, which causes the condition to clear up. Many drugs have been used for the purposes of irrigation. Practical experience speedily reduces the list to some five or six. These include: permanganate of potash 1/8000 to 1/4000, zinc permanganate 1/8000 to 1/4000, oxycyanide of mercury 1/6000 to 1/3000, acriflavine 1/4000 to 1/2000, silver nitrate 1/12000 to 1/6000. Each of the drugs enumerated has certain advantages. Permanganate of potash is the more generally useful. Zinc permanganate is valuable when an astringent action is required in the resolving stages, when the mucus output of the glands of Littré needs checking. Oxycyanide of mercury is valuable when the urine becomes clear with threads, in mild recurrences, and in cases where secondary organisms are more prominent than the gonococcus in the discharge. It should never be used if the patient is taking iodide of potash by the mouth, as intense strangury is caused by the combination in the urine. Acriflavine is very useful in early cases when the urethra is particularly irritable and permanganate of potash cannot be tolerated. It tends, however, to make the mucous membrane very sodden, and should therefore be alternated with zinc permanganate every three days. Indeed, it is a useful practice to ring the changes on whatever drugs are being used. Silver nitrate has its chief value in the later stages when a posterior urethritis is clearing up too slowly.

All irrigations should be given at least once a day at first, and then at gradually increasing intervals as the urine clears up. The temperature of the lotion should be 105° F., and the height of the irrigator about 2 feet above the patient's urethra. Two litres is the usual amount required. A syringe should not be recommended unless irrigation is impracticable. If it must be used, it is required three or four times a day, should be given in the erect posture; and the greatest possible care taken not to force the sphincter.

The question whether the anterior urethra *only* should be washed out at first, or the bladder irrigated right from the start is still a disputed one. Logical treatment suggests anterior irrigation only for the first week, and if no signs of posterior implication then show, the continuance of this procedure. Sixty per cent. of cases are said to develop posterior urethritis within the first three weeks. This I think is much too high an estimate. It certainly does not occur to that extent in the manganese-vaccine cases. Posterior urethritis is indicated in acute cases by frequency, precipitancy, pain, temperature, and usually a decrease in the discharge with some hæmaturia. Such a syndrome cannot be missed; but, unfortunately, in some 50 per cent. of cases the patient complains of nothing more than a little frequency. It is for this reason that many competent urologists recommend bladder lavage from the start; and although I do not recommend this, I must admit that in my experience there does not appear to be any extra risk involved in the procedure, provided that the anterior urethra has been thoroughly irrigated beforehand to get rid of all visible discharge. To irrigate the bladder the reservoir should be 5 feet above the urethra, and the patient instructed to urinate against the pressure of the incoming fluid. With a little practice it will then be found that the sphincter can be taught to relax automatically.

Acute Posterior Urethritis.

Symptoms of acute posterior urethritis should be treated, if possible, in bed; irrigations stopped, hot sitz baths prescribed, and the urine rendered alkaline with sod. bicarb., gr. xx. quartis horis. Suppositories of atropine gr. 1/75 should be given to prevent extension to the epididymis. Only after the condition becomes quiescent should irrigation be resumed. When discharge is lessening down the prostate should be examined per rectum; but massage is not indicated in the inflammatory stage. If the prostate is painful and a little swollen to the touch, manganese butyrate, if not already given, should be tried in a dosage of 1 c.cm. intramuscularly. If, unfortunately, abscess development occurs, it is bad practice to pass a sound in the hope of rupturing it into the posterior urethra—an intractable posterior urethritis generally follows. If it is found pointing towards the rectum, resist the temptation to incise—you will only add a coli infection to the already existing gonococcal one, and may also establish a fistula. The correct procedure is to make a transverse incision in the perineum and drain. Epididymitis quickly resolves under intramuscular injections of contramine 0·25 g., and 10 per cent. guaiacol ointment locally.

Whilst under treatment the urine should be inspected at every visit to gauge the progress of the case. The simplest routine method is Thompson's two-glass test. In this the patient passes his urine into two glasses, one or both of which will show pus whilst discharge is present. As long as the second glass is clear the posterior urethra is probably not involved.

Instrumentation.

When both are clear, with or without threads, the acute stage is over. It is when this stage has been reached, and not till then, that intra-urethral instrumentation is permissible. Diagnostic bougies, sounds, dilators, the urethroscope are all contra-indicated as long as the urine is muddy with pus or muco-pus. Enormous harm has been done in recent years by over-instrumentation, and invaluable instruments such as the urethroscope discredited in consequence.

The Standard of Cure.

No standard of cure in the male is complete that does not include a complete endoscopic examination of the urethra, the passage of a full-sized sound, and the microscopic and cultural examination of the urine before and after prostatic massage on several occasions spread over some months. A large proportion of so-called second and third attacks are merely relapses from a first attack of gonorrhœa that has never been adequately treated because never properly examined for cure.

A REVIEW OF THE PRESENT POSITION OF THERAPEUTIC IMMUNISATION.

BY J. HENRY DIBLE, M.B. GLASG., M.R.C.P. LOND.,
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF MANCHESTER.

VACCINE therapy, the attempt to treat active disease by the subcutaneous injection of killed cultures of the causal micro-organism, has now been before the medical profession for a very considerable period. It has been tried in almost every conceivable malady in one form or another, and in many conditions but for many observers judgment is still suspended as to its actual value. A like phase has existed for a whole host of therapeutic agents, and in recalling these forgotten pages of their history the cynic may find some gloomy satisfaction in noting how repeatedly the final judgment has allowed to them but little utility, or utility in only a very restricted sphere. To-day it is to speak with great moderation to say that the hopes and expectations of the earlier days of vaccine therapy have not been realised. Fundamentally, the doctrine lying behind this mode of treatment has depended upon the specificity of micro-organisms as the causal agents of disease; and in practice this belief in specificity has been pushed to the extent of insistence upon autogenous vaccines in the belief that, for example, the gonococcus from one person's urethra in some subtle way differs from the gonococcus in a second person's and that the autogenous strain is accordingly preferable from an antigenic point of view. This belief, let it be said, does not always rest upon any sound experimental basis. Clinical experience has thrown doubts upon some of these fundamental conceptions. It has been a recurring experience that stock vaccines sometimes give as good, and in many cases an even better, result where good results follow upon vaccine treatment than the autogenous variety and, in fact, that there is in the whole matter an element of uncertainty, difficult to explain if the guiding theory be correct, which makes each application of vaccine therapy an experiment in itself.

Other facts, brought forward from time to time, raise more serious doubts in the minds of their users as to the mode of action of vaccines, and call into direct question the correctness of the theory upon which their employment has been based. Amongst these we may cite the abundantly good results reported from the use of substances derived from organisms by their chemical treatment: partial vaccines, detoxicated vaccines, and residual vaccines, as they are called by their various advocates. These are for the most part prepared by dissolving the bacterial bodies and precipitating a majority of the protein from the solution by means of some protein precipitant. Such substances are said to have antigenic properties and to produce good results in the conditions in which they have been employed. With the benefits obtained we are not immediately concerned, but, if the facts are as stated, they direct a serious blow at the doctrine of specificity and would seem to dispose altogether of the ideas underlying the advocacy of autogenous vaccines. Yet more, repeated accounts are met with in which credit is attributed to vaccines, which are avowedly and altogether non-specific in their action—a vaccine prepared from one organism being productive of good results in conditions definitely due to another. In view of the growing accumulation of fresh facts, directing light upon one or other facet of this many-sided problem, it seems well to summarise and re-survey the whole question in an endeavour to arrive at the present position of knowledge in this field. Within the last few years certain fresh ideas have been put forward which make this all the more necessary, since they introduce conceptions radically different from those which have been so firmly established for a number of years.

The History of Artificial Immunisation.

To go back over the history of artificial immunisation we begin with Jennerian vaccination as the first really successful production of immunity by a modified virus; it is a preventive method, and one which goes out to meet, half-way, the previously practised inoculation. Pasteur's work, from the point of view of the present problems, concerned itself with anthrax, fowl cholera, and rabies, and was in each case directed towards prophylaxis. It adhered to the earlier work of Jenner in the very important principle of producing immunity in the *uninfected subject* by means of a known and living virus, but one attenuated beyond that degree of virulence which is capable of initiating the actual disease. This method, which as far as we can see most closely approximates to the means productive of the most solid variety of immunity known, recovery from the actual disease, is therefore the one which of all possible methods is most likely to convey a substantial degree of resistance to subsequently encountered infection. The step from these procedures to vaccination by means of killed cultures is therefore a very great one. In the new field, which although entered earlier by several investigators, is especially the domain of Sir Almroth Wright, and in which the most prominent investigations have been the delicate in vitro experiments which are peculiarly his own, the application of the principles which this method contains has been widely made with varying degrees of success. Success has been most pronounced in the case of preventive inoculation, notably against typhoid fever, where it has been unequivocal. In another field, however, that of vaccine therapy properly so-called, the attempt not to prevent but to treat the disease in an infected subject, there is an even further departure from the underlying ideas of the Pasteurian method, and here the results obtained have been very uneven and often disappointing. Much water has run under many bridges since the first introduction of vaccine therapy, and in the interval an immense amount of work has been expended in the endeavour to elucidate the mechanism of bodily immunity. This work has given us, in the form of a by-product, certain diagnostic tests of the greatest value in clinical medicine, such as the Widal and Wassermann tests, but there has been little real accretion to our knowledge of the principles of resistance and immunity from the results of workers in this field. Recently certain fresh ideas, bearing upon this problem and consequently upon that of its artificial stimulation, have been put forward which are suggestive.

Tissue Immunity.

One of these is the conception of "tissue immunity," which has been especially brought into prominence by the labours of Besredka, and has received a good deal of indirect support from various sources. As the outcome of experiments upon mouse infections with typhoid Besredka concluded that the only really effective way of achieving immunity in such animals is by bringing the organisms into actual and intimate contact with the normal seat of infection, the alimentary mucous membranes, and that whilst subcutaneous injections gave an extremely mediocre degree of resistance a sublethal infection by the alimentary tract gave a substantial and lasting one. It will be seen that these ideas carry us back very close to the principles of Pasteurian vaccination, which have been in some danger of being lost sight of. This hypothesis has been developed in two directions. Firstly, in practice, a method of prophylactic inoculations has been involved in which the vaccines are administered by the mouth, with special precautions to ensure as far as possible an intimate contact between them and the mucosal cells; a method which it is claimed is applicable to the prevention of diseases of intestinal origin. The procedure is as yet on its trial, but encouraging reports are appearing from France, and Ch. Nicolle, in a few concise experiments, appears to have demonstrated its efficacy in affording protection against dysentery in the human subject. Here, indeed, if its success is proved its greatest sphere of utility should lie, since the violent reactions which the subcutaneous injection of dysentery bacilli occasion practically prohibit inoculation by this route. In the second place, Besredka's work lends support to the theory that in disease immunity is often a special function of a particular tissue rather than one implicating the body cells generally, as we have been perhaps too prone to think, and hence, in the production of artificial immunity, we should proceed in accordance with this principle. In other words, that since certain diseases produce their most striking lesions in given tissues the process of artificial immunisation should be directed towards that tissue and the immunising agent introduced into it, in the case of typhoidal disease into the intestine and its mucosa, in the case of anthrax into the skin; a principle which appears to have long been practised, albeit unwittingly, in the case of vaccination against small-pox. Some direct support for this suggestion comes from the results of experiments upon anthrax, which have shown that the guinea-pig, an animal commonly regarded as very susceptible to this disease, is in reality relatively insusceptible provided that the organisms are introduced into the deeper tissues and infection of the skin is avoided. In accordance with this finding attempts to immunise by subcutaneous injection, even when pursued with the greatest care and persistence, confer, in the case of these animals, only a slight resistance to the infection, but if graduated intradermal inoculations be made a very substantial immunity can be established. This contention of the autonomy of different tissues in regard to disease, and the possibility of the production of local immunity at the site of normal invasion, is an engaging one. Levaditi's experimental work upon encephalitis, herpes, and allied conditions, and Marie's experiments upon vaccinia have tended towards the same conclusions, and in certain cases may extend them to embrace structures related by development from the same embryonic layer. In passing, one may note that the single affection in which it is most generally agreed that the subcutaneous injection of vaccines is most often beneficial, furunculosis, is an integumentary one.

Stimulation of Specific Means of Defence by Non-specific Substances.

Whilst these results may go to show that we have been too readily satisfied with subcutaneous injections in our attempts at therapeusis by vaccines, and to demand a reconsideration of route as well as of type of substance introduced, other work has been going forward which is of special interest in relation to both of these matters and particularly in pointing to the possibilities of the production and provocation of non-specific means of defence. One must readily realise that, from the point of view of bacterial infections, the body is provided with both specific and non-specific, or general, means of defence. Phagocytosis is essentially non-specific: available against the majority of bacterial invaders. The more complex serological reactions are essentially specific: developed only in response to the presence of individual types of organisms. It is to be remembered that these latter are only demonstrated by such techniques as we possess, and we have no knowledge as to whether it is an enormous or a relatively slight concentration which can be revealed by the methods available. It is quite possible that many of these antibodies may be normally present but in insufficient concentration to be shown by the means we can dispose. Although most of the serological reactions are, as we see them, essentially specific, it must not be forgotten that non-specific means of defence most certainly exist in the body fluids and that we have perhaps been led, by the attractiveness of the opsonic theories and the usefulness of the serum tests, rather to lose sight of these means of defence and to forget the possibility of stimulating them by other ways than by vaccines derived from the causal organisms. There are, therefore, two possibilities to be considered. One is the stimulation of the specific means of defence by non-specific substances; the second is the stimulation of more generally applicable, non-specific, protective substances and the methods of doing this. With regard to the first case, striking evidence of its possibilities has been brought forward by Walbum and Mörch in Madsen's laboratory. It has been found that the intravenous injection of manganese chloride provokes, in horses used for the production of diphtheria antitoxin, a marked augmentation in the amount of this substance in the blood; this takes place within a few hours of the injection; similar experiments upon the production of agglutinins have given results of a like nature. It is perhaps significant to recall at this juncture the present widespread use of colloidal manganese in the treatment of localised septic foci.

Stimulation of Non-Specific Protective Substances.

In connexion with the second of the two therapeutic possibilities enumerated above, some very striking results recently obtained by Sir Almroth Wright call for attention. Wright has found that the addition of a culture of organism to blood, outside the body, causes a liberation of anti-substances, occurring rapidly and at once, which results in the blood becoming highly bactericidal. Following out these observations, it has been further found that the same phenomenon takes place where the vaccine, in appropriate dose, is injected into the blood-stream of a living animal or man. The result is a sudden increase in the bactericidal power of the blood, which is general in nature and effective for other species besides that of the organism used in making the injection. There is here, therefore, a reaction of a type quite different from those with which the serologist usually works. It is no question of a slow development of agglutinins, complement-fixing bodies, or the like, in response to a specific infection, but a rapid and immediate outpouring of bactericidal substances available for the destruction of a number of bacterial species. Wright holds that these substances are derived from the leucocytes, a source of origin for all humoral anti-substances invoked by Metchnikoff many years ago; and it may be relevant to recall here the marked effects produced upon the leucocytes by injection of peptones and a variety of other substances, as well as the maximum degree of the same phenomenon which is seen in shock associated with intravenous injections in anaphylaxis. This line of thought may link up these phenomena with the striking results claimed from time to time, especially during the war, for intravenous injections of eusol, alkalies, and other substances, in desperate cases of sepsis, and to suggest that these bodies produce their beneficial results not by any direct action upon the bacteria but by their action upon the leucocytes.

Non-Specific Protein Therapy.

Non-specific protein therapy, which has its vogue in therapeutics, is probably another example of the same phenomenon. These varied observations may seem on casual inspection to be isolated and unconnected, but to the writer it seems that there is a general underlying idea running through them all, and that the mechanism of bodily defence and recovery is in process of being made more plain by such various investigations which from different sides are converging upon the same central idea. They are nearly all as yet in the tentative stage, and require a great deal of further development and classification, but they are tending towards knowledge and towards the ultimate removal of the easy reproach, from which the vaccine user cannot yet escape, of "injecting a substance, of which you know little, into a body of which you know less."

HEALTH OF THE NAVY IN 1921.[1]

EIGHTEEN months ago, when we examined the last of these reports,[2] that for 1915, we hoped soon to see that for 1916. Now, 18 months later, we get the report for 1921, and notice that the Admiralty has decided to cancel the preparation of reports for the years 1916–20. This regrettable decision interrupts a series which, completed by the volumes to 1929, would have been continuously published for 100 years; moreover, there are reasons why the decision is particularly unfortunate at this time. The price of the Blue-book has fallen a little; the last cost 7*s.* 6*d.*, this, though slightly larger, costs 6*s.* 6*d.*; smaller type for the tables might still further economise space and paper. The interesting comments on the occurrence of diseases from the reports of medical officers are cut down drastically this year; the statistics have been rearranged in accordance with the 1918 nomenclature of diseases; cases of syphilis are now classed as "first" or "second record," and pneumonia is named "pneumococcal infection (lungs)," and gonorrhœa becomes "gonococcal infection, acute." The "total force" employed and reported upon had fallen from 236,500 in 1915 to 110,700 in 1921. Wounds received in action were 15, eleven among the marines in Ireland, the other four in the Yang-Tse River; 57 men were lost in the distressing disaster to submarine K5.

For every 1000 men employed there were 583 cases of disease or injury (91 of them injuries), with 23·2 invalidings and 3·58 deaths. Venereal disease has greatly increased both in number of cases (113 against 67) and duration of each case (26 days against 14). There is also greater loss of service this year from influenza (31 cases per 1000 men), malaria, Mediterranean fever, and scabies. About the same are the infectious fevers, tubercle, diseases of the eye, ear, and nervous system (though there are only half the cases of insanity that occurred in 1915, during the war), while meningococcus infection has almost disappeared, and enteric fevers, pneumonia, rheumatic fever, and diseases of the digestive system (tonsillitis is one), and of the skin are all materially less. On the whole, a very considerable reduction of the number of cases of illness in the Navy, apart from venereal disease, since 1915. The "sick daily" figure has risen from 22 to 25 for every 1000 men, but if venereal cases are in each year deducted, there is really a fall, from 19 to 17. In other words, the sickness for which medical officers are responsible has considerably decreased.

Invalidity in Various Groups.

The naval forces as arranged in the tables fall naturally into three great groups, the fleet at home, the Atlantic Fleet (29,050 men); the Fleets Abroad (26,950); and the Home Station (54,700), which, with some ships, includes also the depôts and the training establishments. These all together constitute the "total force" (110,700 men), from which are still excluded for no obvious reason the 5480 men at Marine Headquarters, whose particulars of illness are given in two separate and not entirely consistent tables on pp. 174 et seq. and p. 188.

In the great groups mentioned the highest proportion of loss of service by illness is shown by the fleets abroad, which suffer more than the others from venereal disease and injuries, while the healthiest is the Atlantic Fleet, with less than half the complement coming on the sick-list during the year, and an average loss of service of 6·8 days per man. The most important health statistics of these groups can be seen in the accompanying table, though it must be remembered that all the sick-rates are merely crude sick-rates, with no standardisation for ages.

Health Statistics in the Groups.

—	Training estab.	Atlantic fleet.	Fleets abroad	Home station	Total force.	Marines at H.Q.
Number in group.	3637	29,050	26,950	54,700	110,700	5480
Wounded or killed in action	—	0·03	0·28	0·34	0·24	2·18
Other injuries	100	86·9	112	82	91	141
Venereal disease	[illegible]	107	179	81	113	52
Other diseases	1200	290	427	404	379	459
Total cases (Disease and injury)	1299	483	720	569	583	653
Invalided ..	61	17·9	28	32	23	45
Dead	6	4	4·4	2·9	3·6	1·6
Sick daily ..	77	18·6	29·9	27	25	21
Loss of service per man in days	14·7	6·8	10·9	9·9	9·6	7·9
Loss of service, less venereal disease ..	—	4·6	6·6	7·2	6·7	6·5
Individual Diseases.

Rheumatic fever	18·4	1·7	2·3	2·5	2·3	3·8
Tuberculosis ..	—	2·3	2·3	2·4	2·4	3·6
Appendicitis ..	—	3·3	3·7	3·6	3·6	—
Catarrh	—	53	63	78	68	140
Tonsillitis ..	—	24	35	38	33	23
New cases						
Chancroid	—	12	33	8	15	4
Syphilis (1st record)	—	12	17	8	11	5
Gonorrhœa (acute)	—	58	89	46	60	22
Total ..	—	82	139	62	87	31
Scabies	43	27	18	40	31	28

Among the individual diseases dysentery has almost disappeared, and enteric fevers appear to have been, for the time at least, mastered by inoculation. The case-mortality, too, which was 23 in 1911, has been reduced to 15 per cent. Malaria had a serious increase, and Mediterranean fever is again increasing. Meningococcus infection was hardly seen. Pneumonia is less prevalent than in former years. Rheumatic fever shows only half as many cases as in 1915, and those are milder. They only last 20 days, and few are invalided or die. Tuberculosis claimed 264 cases, 247 invalids, and 31 deaths, the figures per 1000 working out to 2·38 cases, 2·23 invalids, and 0·28 deaths. The figures ten years ago were very little different. Among the larger groups, cases and invalidings were heavier in the "Marines at Headquarters," but incidence was greatest upon writers (8·77), followed by victualling ratings (4·49), the sick-berth staff coming this year only third with 4·27 per 1000. They had 6·82 in 1911 and 5·42 in 1915, so they have made a distinct improvement, that will, we hope, increase.

Venereal Disease and Malignant Disease.

Venereal disease (9636 fresh infections, 2907 later cases, 143 invalids, 56 deaths) has reasserted itself since the war, and cases are now about as frequent as in 1911. Some medical officers ascribe the increase to drink and carelessness about preventives; Constantinople and the many unfortunate Russian women there, made refugees by the war, and "dependent on prostitution for a livelihood," had a particularly evil influence. At Simon's Town

---

[1] Statistical Report on the Health of the Navy for 1921. London: H.M. Stationery Office. 1924. 6*s.* 6*d.*

[2] THE LANCET, 1922, ii., 1032.

"no houses are used . . . and intercourse carried out clandestinely in the open," which shows how prevalent prostitution is there. But all kinds of venereal disease were most increased in China, though Hong-Kong shows improvement. Cases in the Atlantic Fleet are double what they were in the Grand Fleet in 1915 (107 against 53 per 1000); the increase is least among Marines at headquarters. Syphilis, first record, shows the greatest increase. Venereal disease now accounts for nearly one-third of the days' sickness of the Navy, and more than a third of the days in hospital; it is a frightful expense. Surgeon-Commander L. Kilroy is complimented on his initiative which established a routine of treatment (see THE LANCET, Dec. 31st, 1921) with benefit to the patients and economy to the service. Diseases of the eye and ear cause much invaliding, particularly in the first year of service, as latent defects are manifesting themselves under training. Appendicitis shows an unexplained increase; skin diseases are fewer, but scabies has increased along with venereal disease. Malignant disease shows a decrease from 1915, when the incidence (0·37 per 1000) was higher than ever recorded before in the Navy; in 1921 it is 0·22. The rise began about 1909, and in the last ten years the prevalence has been, roughly, double that in the preceding decade. We have no figures for the years since 1915, and it is for this reason that we particularly regret the decision of the Admiralty to cancel preparation of the reports for 1916 to 1920. During the preceding years the rate had been rising rapidly on the whole, though with considerable fluctuations from one year to another. For want of the intervening reports we are unable to decide whether the low figure this year signifies a cyclic diminution of malignant disease in the service in the last few years or merely a drop for a year in the activity of a pathological process which is gaining more hold as the time goes on. The solution of this question has interest far outside the Navy, for it is constantly questioned whether the numerical increase in deaths from malignant disease, which is allowed by all to be occurring, depends on some special activity of, or increased susceptibility to, malignant disease, or to the greater age nowadays of the population at risk. In the Navy we are no longer told the age of the men in the service, but we will probably not go far wrong if we conclude that the service is no older, but rather a little younger than before. And yet malignant disease has certainly, on the official figures, increased its incidence from, at a rough average, 0·13 per 1000 in the ten years before 1909, to something so much larger in the succeeding years that a rate of 0·22 in 1921 looks like a drop. Perhaps a cancer research fund might help the Admiralty to get the statistics for the lost years prepared.

The Health of Younger Sailors.

As to the training establishments and the health of the young, so apt to be the test of sanitary administration, the tables and statistics are again a little confusing, for the numbers given on pp. 95 and 182 do not agree.

		P. 95.	P. 182.
Boys ..	.. *Impregnable*	1660	1153
Boys ..	.. Shotley (*Ganges*) ..	2240	1914
Youths..	.. *Vivid*	570	570

Again, the number of cases of pneumonia from *Impregnable* is stated, on p. 22 as 18, on p. 182 as 13 per 1000; but these figures correspond to a total complement of 1384. Which of these three figures is correct? In any case there has been a marked improvement this year, for in 1915 there were 30, but in 1921 only 12 cases of pneumonia per 1000 in the training establishments reported upon. What is wanted, however, is a statement of the sickness that occurred in all the training establishments for recruits, cadets at Dartmouth, boys and youths, boy and other artificers, marine, and also stoker recruits. The individuals here reported upon would be excluded from the Home Station tables, which would then represent more exactly the health conditions of the working Navy, which has become accommodated to its work.

Apart from the serious increase in venereal disease, the great question that emerges from the study of this report seems to be: Why does the incidence of tuberculosis on a population of young, strong men, well-clothed, well-fed, well-housed, remain so persistently the same, in spite of every effort?

MALARIA IN MAURITIUS:

A STUDY OF ANOPHELINES.

MAURITIUS has always been interesting from the entomological standpoint. Its remoteness from any of the large land areas of the world has tended towards specialisation, while its communications with Africa on the one hand and Asia, more particularly India and Ceylon, on the other, have led to its exhibiting both African and Oriental species of insect.

Introduction of the Malaria-Vector.

Possibly the most notable event in its entomological history is the supposed introduction of the well-known African mosquito and malaria-vector, *Anopheles costalis*, somewhere about the late 'sixties of last century. If such an event really did occur it was fraught with momentous and disastrous results for the colony, because it was followed by the severe and classical outbreak of malaria which slew well-nigh 32,000 people and drove the European settlers from the coastal belt to the inland heights. Ever since those terrible fever years of 1867–68 malaria has exercised a malign influence on the health and happiness of a large section of the population, has seriously interfered with the economic development of the island, and has been a source of much trouble and expense. The evidence as to the introduction of *A. costalis* has, naturally enough, never been conclusive. In 1867 the association of mosquitoes with malaria was unknown, though not unsuspected, and the malarial parasite had not been determined. Hence we shall never learn definitely how much credence is to be attached to a hypothesis which at first sight appears to have a good deal in its favour and which is discussed at some length in the reports of Ross, Fowler, and Balfour. It is possible that this mosquito has existed for centuries in Mauritius, that malaria was always present there in an endemic form, and that the great epidemic was due to causes other than the chance introduction of *A. costalis*. The new report on the *Anophelinæ* of Mauritius by Malcolm E. MacGregor, entomologist to the Wellcome Bureau of Scientific Research, while it does not clear up the above question, is a most important document and indirectly may be said to shed light on the matter, for it records the discovery of a new African anopheline, *A. funestus*, in Mauritius, regarding which the same problem arises—i.e., has it been there for hundreds of years or has it been recently imported?

Mr. M. E. MacGregor's Visit.

Mr. MacGregor visited Mauritius as the outcome of the inquiries into the medical and sanitary condition of that colony conducted by Dr. Andrew Balfour in 1921. The latter realised that our knowledge as regards the bionomics of the Mauritian anophelines was defective and that it was very necessary to undertake an extensive entomological inquiry combined with intensive anti-malaria work. He submitted a scheme of operations to the Colonial Office, but after consultation with Dr. Guy Marshall, Director of the Imperial Bureau of Entomology, it was decided to institute a preliminary inquiry on a smaller scale. Dr. Balfour had noticed that there was a marked difference in the summer and winter distribution of *A. costalis*, and, owing to the great restriction in the breeding places of this mosquito during the winter months, had suggested that an intensive campaign against the water stages of the mosquito during this season would probably yield important results. He did not think that *A. costalis* hibernated during the cold weather in Mauritius and therefore believed that conditions were favourable for the type of campaign he advocated. Dr. Marshall considered that further information on the important question of hibernation should be obtained in the first instance and, as a result, Mr. MacGregor undertook the work fully detailed and admirably illustrated in his report. He confirmed Dr. Balfour's views as regards hibernation and the advantages of intensive winter operations against *A. costalis*, but he accomplished much more, for not only did he, as stated, discover that *A. funestus* is an inhabitant of Mauritius, but he made careful and valuable observations on the bionomics of the four species of Mauritian anophelines now known to exist, determined their malaria-transmitting powers, advanced a scheme for their suppression, and discovered in Mauritius no less than 11 species of culicine mosquitoes, hitherto unrecorded from these islands, and one of which, *Ædes mascarensis*, is new to science. He also made a survey of the neighbouring island Dependency of Rodrigues, determined its culicine fauna, and made recommendations with respect to safeguarding this colony from malaria.

A Missed Species.

All these matters and several others of less importance are dealt with in his report, which is divided into two parts, the first dealing with the malaria and mosquito question in Mauritius from the ætiological and bionomical standpoints and devoting also a few pages to conditions in Rodrigues; the second concerned with the scheme for an anti-malaria campaign based to a large extent on the new facts determined as a result of his inquiry. There could be no better example of the value of the work of the trained field entomologist. Take MacGregor's discovery of *A. funestus* in Mauritius. From the evidence he furnishes it is almost certain that this mosquito eluded Ross, Fowler, and d'Emmerez de Charmoy in 1908, while it was also missed by Balfour in 1921, who, however, as MacGregor points out, had a multitude of matters requiring his attention and was unable to concentrate on entomological work. It is scarcely surprising that Ross and his confrères did not encounter the wily *funestus*, for their investigations only occupied three months, and it was not until four months had passed that MacGregor, almost, as it were, by chance stumbled on a larva strange to Mauritius. His account of the discovery and of his further quest for the species savours of the dramatic. He says :—

> "On Oct. 11th my scientific assistant, Mr. Gébert, and I were searching in Mare Rohan Pointe aux Sables for the rarer culicine species, when suddenly a small black anopheline larva was found in one of the 'dippers' that had been thrust down at the roots of a small species of bulrush which covered the marsh. I examined the larva carefully by means of a hand-lens, and could see at once that we had apparently found a species that had not been observed in Mauritius before. Continued search in the marsh at this point failed to give us others, so I placed the larva in a collecting tube and returned with it in my motor-car to the laboratory at Reduit without further delay. Examination of the larva under the microscope disclosed the fact that it was undoubtedly the larva of a new anopheline species, and I suspected the larva as *Anopheles funestus*. It was placed carefully aside to undergo its metamorphosis, and as it was fortunately then in the late fourth instar, it pupated and emerged successfully four days later. Examination showed that my surmise was correct and that the emerged specimen was a female *A. funestus*.
>
> Highly astonished by our find, Mr. Gébert and I proceeded again to Mare Rohan to search the marsh from end to end. First searching where the larva had been discovered we could find no others, but later on when we had got to about the middle of the marsh where there was more open water on which, floating half submerged, were numerous dead cocoanut palm leaves, we found enormous numbers of *A. funestus* larvæ, pupæ, and eggs. It became evident that the larvæ and pupæ were to be obtained in largest numbers when we 'dipped' *under* the floating cocoanut leaves."

Later he describes finding *A. funestus* elsewhere, and records a remarkable observation regarding the habits of its larvæ :—

> "My assistant and I, who had first noted the fact that the larvæ at Mare Rohan seemed to hide under the leaves of the floating cocoanut palms, started our investigations on the bionomics by searching the recorded breeding places under all floating vegetation. We soon found that the larvæ could most readily be obtained in this manner, but the numbers we succeeded in capturing were disappointingly few. One day while searching a small backwater pool on the Tamarin River (Black River District) where the water was shallow, and where numerous flat leaves of a water plant dipped below the surface, we found that by dipping under the leaves and close against the bank of the pool, large numbers of the *A. funestus* larvæ were obtainable. By dipping in any other way, even only a few inches from the bank, not a single larva could be found.
>
> Stopping my work and remaining motionless where I stood, I stooped and peered carefully down at the weeds near the bank. Greatly to my surprise, I saw scores of *A. funestus* larvæ ranged in lines lying on the water surface as close in to the bank as it was possible for them to get. A movement on my part which disturbed the vegetation caused some to dive, and many *to wriggle up out of the water on to the wet leaf surfaces.* Resuming a motionless position, I noticed that after the lapse of a minute or two these larvæ would wriggle down to the water once more, and, with the others that had dived, would in time, if not again disturbed, swim a few yards away from the bank. The slightest movement, such as treading lightly on the ground, was sufficient to alarm the larvæ, and they would dart to the bank, and if further alarmed would either dive or climb up the leaves once more.
>
> The explanation why it was that we had overlooked *A. funestus* while searching for the larvæ of *A. costalis*, *A. maculipalpis*, and *A. mauritianus* was then obvious; for the three latter species, like most anopheline larvæ, are easily captured by dipping in the open water or near the banks. The larvæ of *A. funestus* by taking refuge far in at the extreme edges of the ponds, marshes, &c., are almost safe from the dippers when these are used in the ordinary way."

MacGregor is inclined to think that *A. funestus* may have been introduced comparatively recently into Mauritius from Madagascar, but he admits that it and the other three anophelines, *A. costalis*, *mauritianus*, and *maculipalpis*, the last of which he found to be exceedingly numerous in many places, may have existed on the island for centuries. His discovery of *A. funestus* has much hygienic importance, for this anopheline in its developmental stages prefers shade, whereas *A. costalis* shuns it. At the same time, it is fortunate that the distribution of *A. costalis* is conterminous with and overlaps that of *A. funestus* so that no extension of anti-mosquito measures to *new localities* is required.

Seasonal Distribution of Anophelines.

The following table presents in a concise fashion the variation in the summer and winter distribution of the four anopheline species :—

WINTER.	SUMMER.
Anopheles mauritianus. Dispersion : From the coast to the highest altitudes all over the island. Large numbers of larvæ, pupæ, and adults obtainable.	*Anopheles mauritianus.* Dispersion : As in winter. Numbers obtainable not noticeably changed.
Anopheles maculipalpis. Dispersion : Restricted to special types of breeding places from the coast occasionally up as high as 1200 feet. Considerable numbers obtainable.	*Anopheles maculipalpis.* Dispersion : As in winter. Numbers appreciably increased.
Anopheles costalis. Dispersion : From the coast to 1200 feet at many places. Large numbers obtainable at lower altitudes, and very few near the altitude of 1200 feet. Found once at 1800 feet (Forest Side).	*Anopheles costalis.* Dispersion : From coast to 1800 feet (in cattle hoof-holes at Forest Side). (Dagoutiers, Parc aux Cerfs, and Quartiere Militaire, 1500 feet.) Numbers very greatly increased, both at the coast and inland areas.
Anopheles funestus. Dispersion : From the coast, but not above an altitude of 500 feet. Large numbers obtainable at the coastal belt.	*Anopheles funestus.* Dispersion : From the coast to 500 feet (Valton estate).

The author lays much stress on what he calls the "inland winter refuges" of *A. costalis*. Indeed, his plan of campaign, which cannot be here detailed, centres round these limited specialised breeding places. He regards the outlook in connexion with the suppression of malaria as hopeful provided, and this is all-important, that those in charge of the operations are independent of, though working in close association with, the local medical and health department, and that public interest and sympathy are aroused by appropriate propaganda work. He agrees with Balfour that the present malaria statistics are entirely unreliable, that the recorded mortality from malaria is fallacious, but that malaria is undoubtedly an important economic factor in the welfare of the colony.

Mauritius and Rodrigues.

He contrasts Mauritius with Rodrigues. There is no malaria in the latter for there are no anophelines there, and its inhabitants compare in general health and physique very favourably with the malaria-saturated Creoles and Indians of Mauritius. He explains how the barrier coral reef by keeping vessels off shore has indirectly prevented anophelines reaching the island, and he puts forward a strong plea against the project of building a jetty from Port Mathurin out to the edge of the reef. Such a development would almost certainly abolish the immunity Rodrigues enjoys as regards both anophelines and malaria and would be a disastrous undertaking. It is to be hoped Mr. MacGregor's recommendation will not go unheeded.

There are many other matters of interest in this valuable contribution to the literature of mosquitoes and malaria. It should be read and studied by all interested in these kindred subjects and also by those who, in virtue of their official position, are charged with the double duty of safeguarding and benefiting the public health of tropical communities.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

"Papa" Pinard.

THE Chamber of Deputies has elected as its President with great unanimity, Prof. Pinard, the veteran obstetrician, whose playful title of "papa" is in acknowledgment of his having brought more than 20,000 children into the world. At the outbreak of hostilities in 1914 Pinard relinquished a brilliant university career to coördinate all the child welfare agencies in Paris. A central office was instituted at the Maternité, from which went out a band of devoted voluntary workers; and during the first four years of the war nearly 14,000 pregnant women were cared for in municipal or private homes, and another 13,000 nursing mothers in refuges where they could remain until their infants were weaned. Pinard is regarded indeed as the founder of puericulture in France and as the one who saw clearly the fearful threat to child-life involved in the absorption of married women into factories. Retiring in 1920 under the age-limit from the chair of puericulture in the Medical Faculty, he became a deputy in the new chamber and at once propounded there a scheme for an enormous nursery to accommodate 1500 children with their mothers, a scheme which enlisted the sympathy of the Minister of Hygiene, Mr. Breton. Prof. Pinard celebrates this year the eightieth anniversary of his birthday and his jubilee as a member of the medical fraternity.

Aneurysm of the Internal Carotid.

Dr. Rouvillois, of the school of military health service at Val-de-Grâce, recently reported to the Academy of Medicine a case of arterio-venous aneurysm in the intracranial portion of the internal carotid artery. The formation of this aneurysm was due to a somewhat rare cause. The cause of arterio-venous aneurysm is usually a direct injury to the vessels, but in this case not even the slightest wound was to be found either in the neck, mouth, or pharynx of the patient, who was 22 years old. He had been flung forcibly to the ground by the bursting of a large shell, and following this violent trauma the signs of aneurysm appeared. It is therefore logical to suppose that an arterio-venous communication was caused by the violent contusion, an uncommon occurrence. Complete recovery followed the operation of applying a quintuple ligature and completely removing the aneurysm. The aneurysm itself consisted of an arterial sac, in addition to the arterio-venous communication, which was adherent to the wall of the pharynx.

The Therapeutics of Long Sea-Voyages.

In a recent communication to the Academy of Medicine the port sanitary officer of Havre, Dr. Adrien Loir, recalled the large number of works published in England before 1890 dealing with the therapeutics of long sea-voyages. At that time long sea-voyages were widely advocated by English doctors, and remarkable results were achieved. French doctors, Dr. Loir urged, should make themselves familiar with the question which was so carefully studied by Dr. J. Burney, Dr. A. Crosbee Dixon,[1] and others, in particular Dr. Hermann Weber and Dr. A. Parkes Weber, while in 1892 further articles on this subject had appeared in THE LANCET. While in England on a mission on behalf of the League of Nations Dr. Loir studied this literature and commends the investigation of the therapeutics of long sea-voyages to his colleagues.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Bacterial Purification of Rivers.

AN unusually interesting programme was enjoyed by the Society of Hygiene of Johns Hopkins University on May 12th. Dr. W. H. Frost, professor of epidemiology, discussed bacterial purification in the Ohio river, a study of which was undertaken by the U.S. Public Health Service some ten years ago. A maximum bacterial count was found not at the sewer outfalls (of which there were six in the portion of river studied), but some 12 hours lower down the river. This may possibly be due to breaking up of clumps of bacteria; Dr. Frost did not consider it probable that there was any multiplication of bacteria in the water. Attempts to fit curves to the observed decrease of bacterial counts were most successful when the counts at the actual sewer outlets were disregarded. Curves then showed that purification takes place at a diminishing rate. Observations in winter months showed further that the purification takes place more slowly at lower temperatures. These experimental studies are to be continued.

Experimental Measles.

Dr. Joseph M. Scott presented a report of the experimental work on measles which he is doing in collaboration with Dr. Charles E. Simon. Filtered washings of swabs from measles throats were injected intravenously into a series of rabbits. Daily swabbings were taken and an injection into rabbit made each day from each of six members of the family in which measles cases were occurring. Passage of the virus through a series of rabbits gave a virus of fixed character producing elevation of temperature, leucopenia, relative decrease in polymorphs, and relative increase in basophils. Exanthems and enanthems were not noted, nor was erythema. They consider it essential to make differential blood counts to determine measles infection in the rabbit. Rabbits that have had "measles" are found to be immune to the virus. Three out of five rabbits contracted "measles" from exposure in the same cage with experimental animals that had been infected intravenously. Attempts to obtain infective virus from the dust and air in the vicinity of measles patients gave negative results, but material from secretions of nasopharyngeal membranes of measles patients gave constantly positive results. Even when the material had been allowed to dry on the handkerchief for as long as four days, positive reactions in rabbits were obtained. A very satisfactory series of control experiments adds to the value of the results obtained. Further experiments will be undertaken to determine the period of viability of the virus in the throat and on material outside the body. So far, 180 rabbits have been inoculated. Three monkeys inoculated with the rabbit virus produced a characteristic eruption in one case, and rise of temperature and leucopenia in all three. In the discussion Dr. Simon emphasised that the twentieth rabbit in a series of rabbit-to-rabbit infections acquired immunity to an active human virus which produced a typical reaction in control animals.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Milk Injections in the Treatment of General Paralysis.

ENCOURAGED by the results described by Prof. Wagner-Jauregg, of the Vienna University, in the treatment of G.P.I. with the protein therapy and inoculation of malaria, some Hungarian neurologists have given a trial to this new method. Particular interest attaches to the fact that the experiments were carried out in the clinic of Dr. Moravcsik, director of a large psychiatric institute and lecturer on nervous and mental diseases in the Budapest Royal University, his clinic being known for more than 30 years as being strongly conservative. The experiments were begun in 1920 with tuberculin, and then an interesting chance directed attention towards milk injection. A patient, suffering from advanced general paralysis, had a carbuncle on his neck, which had been incised and bandaged. The patient, however, had torn off the bandage and smeared the wound with fæces, causing an extensive inflammation round the wound, with gangrene of the edges. As this condition aggravated his mental state, a surgical specialist was consulted, who recommended the application of milk. The patient was given 10 c.cm. of sterilised milk under the skin of the abdominal wall on October 19th, 1920; the same day he had a temperature of 40° C., which subsided on the following morning. From this time onwards his wound improved rapidly, and his bodily strength began to return. Within one month his wound was totally healed. In December his mental condition began to improve, his restlessness ceased, his behaviour showed ever-increasing coördination, and on Feb. 21st, 1921, he left the clinic quite composed. Doubtless, the chief factor in the patient's improvement was the long-continued suppurative process, nevertheless the change in the patient's condition after administration of the milk injection was so striking as to merit further study, and the doctors of the clinic felt entitled to experiment more extensively with the injections. By this method they treated 40 cases of general paralysis, many of chorea, and several of epilepsy. Dr. Moravcsik stated that he felt justified, in view of the results obtained, in considering milk to be the most efficacious of the non-luetic therapeutic measures (milk, phlogetan, and tuberculin) administered at the clinic, and that the results of milk therapy were much superior to those of antisyphilitic treatment in G.P.I. He considered milk to be a very valuable addition to the scantily furnished armamentarium against general paralysis. In ten cases of chorea minor the milk protein therapy gave excellent results. The explanation of the efficacy of protein therapy, in that it is due to leucocytosis, activation of the protoplasm, stimulation of antibody-forming elements, increased transfusion and hyperæmia in the diseased foci, &c., is at present only theoretical, and must be confirmed by further and more detailed experiments. On a parallel with this, Dr. Moravcsik contends, protein therapy must be applied on a wider scale in nervous and mental diseases. The ultimate value of the treatment can only be decided after extensive clinical experiment.

Soap Inunction for Lung Diseases.

The Central Tuberculosis Dispensary of Budapest has made extensive experiments on the efficacy of turpentine soap ointment, a method of treatment which has been much recommended by some continental authorities. Dr. Aladar Bathory, who controlled the experiments, employs the following composition :—

℞	Potash soap		
	Yellow vaseline ..	āā	15·0 g.
	Carbonate of potash		0·5 g.
	Beechwood creosote.		
	Turpentine oil.		
	Camphorated oil.	āā	3·0 g.
	M. fiat ung.		

This is quite a soft ointment, with which the back, chest, and arms of the patient are anointed every alternate day. It is advisable to have the inunctions made by a nurse, and about a teaspoonful of the ointment is applied at one time. Dr. Bathory selected for treatment such patients as were not suited to specific treatment, owing to high fever or to extensive destruction of the lungs. His results were as follows: After one or two weeks' treatment the patient's subjective symptoms improved considerably, the temperature was lowered, and in some cases reached normal. There was decided improvement in the patient's outward appearance; facies and gait showed greater tone. Those who had come for treatment with an escort were able in two or three weeks to come alone. In one case extensive œdema of the lower limbs disappeared completely, the cough was greatly reduced, and the appetite increased. The disappearance of catarrhal rhonchi in the lungs was striking. As regards the effect of the treatment on the skin, nothing was to be noted beyond a slight hyperæmia. No disturbing symptoms were shown either by the kidneys or other organs. Further investigation into this method is being carried out at this institution.

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. G. Nunn and Surg. Lt.-Comdr. F. L. H. MacDowel to the *President* for hospital course.

Surg. Rear-Admiral Sir A. Reginald Bankart is placed on the Retd. List at own request to facilitate the promotion of junior officers.

ROYAL ARMY MEDICAL CORPS.

Capts. G. Fleming and A. K. Forbes retire receiving a gratuity.

Lt. L. F O'Shaughnessy resigns his commn.

TERRITORIAL ARMY.

C. R. Dudgeon (Maj. R.A.R. of Off.) to be Capt.

Supernumerary for Service with O.T.C.—Capt. (Bt. Maj. J. B. Orr, from Gen. List, to be Capt. (Bt. Maj.) and to command Inf. Unit, Aberdeen University Contgt., O.T.C.

Lt. C. S. Atkin to be Capt.

ROYAL AIR FORCE.

R. T. F. Grace is granted a short service commission as a Flying Officer.

F. S. S. Whiter (temp. Lt., Dental Surgeon, General List Army) is granted a temporary commission as a Flying Officer on attachment to the R.A.F.

INDIAN MEDICAL SERVICE.

Lt. Col. A. Hooton to be Major-General, and Lt.-Col. T. B. Kelly to be Col.

Capt. D. C. McNair relinquishes his tempy. commn. and is permitted to retain the rank of Capt.

The King has approved the retirement of Col. Bhola Nauth.

INDIAN MEDICAL SERVICE DINNER.

The annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 18th, Colonel J. J. Pratt in the chair. Tickets and all particulars may be obtained from the honorary secretaries, 63, Addison-road, Kensington, W. 14.

Public Health Services.

INQUIRY COMMITTEES ON THE CONDUCT OF PANEL DOCTORS: A QUESTION OF PROCEDURE.

Before a Divisional Court recently the Attorney-General appeared to show cause against a rule nisi obtained by two medical men, practising in partnership, Drs. A. B. and C. D., who sought to quash an order of the Ministry of Health directing that £1000 should be withheld from the remuneration payable to them by the Insurance Committee in respect of their panel patients. The name of each doctor appeared on the Lancashire Insurance Committee's panel, but only Dr. A. B. had a list of insured persons, the other partner, Dr. C. D., acting as Dr. A. B.'s deputy when attending these patients. Complaints having arisen that the doctors were improperly charging fees to insured persons, an investigation by the Medical Benefit Subcommittee under Part V. of the Medical Benefit Regulations was instituted into the complaints against Dr. A. B. only. On a consideration of the report of this subcommittee, the Minister suggested that the Insurance Committee should make representations under Part VI. of the Regulations in respect of *both* doctors that their continuance on the panel was prejudicial to the efficiency of the insured. The committee made representations accordingly, and the Minister appointed an inquiry committee. On consideration of the inquiry committee's report the Minister decided that the doctors' names should not be removed from the medical list, but that £1000 should be withheld from their remuneration.

In his opening speech against the rule the Attorney-General submitted that it was a fundamental principle of the National Insurance system that medical practitioners under it should be paid by capitation fees and should accept no other remuneration from their panel patients, except in accordance with Regulations. He expressed the view that the court would have no desire, if it should be found to have the power, to review the discretion of the Minister or to inquire into the severity of the penalty imposed. The points at issue in the case were technical matters relating to the procedure adopted. The question was whether an investigation by the Medical Service Subcommittee under Part V. of the Regulations was a condition precedent to the holding of an inquiry by the Minister under Part VI. of the Regulations. He submitted that the investigation under Part V. had nothing to do with the inquiry under Part VI. Sir William Finlay, K.C., who represented the medical men in support of the rule, pointed out to the court that only technical points were open to him and that he was precluded from going into the merits of the case or into the amount of the penalty. A preliminary investigation had been held under Part V. of the Regulations into complaints against Dr. A. B. only. This had been followed by an inquiry under Part VI. into the conduct of both doctors. As there had been no investigation by the Medical Service Subcommittee under Part V. in respect of both doctors, there had been no proper inquiry under Part VI. On behalf of Dr. C. D., it was argued that as he had no list of insured persons, but merely acted as Dr. A. B.'s deputy, he had not treated insured patients under the terms of a contract with the Insurance Committee and that no representations against him could be made to the Minister. After the arguments of counsel had dealt with the technical points involved at some length, the Lord Chief Justice, in giving judgment in discharging the rule nisi, said that the contention had not been pressed that an investigation by the Medical Service Subcommittee under Part V. must necessarily precede every inquiry under Part VI., but it had been argued that a representation by an insurance committee with regard to an inquiry under Part VI. could only be made as provided in Part V. 30 (2)—i.e., in the committee's report to the Minister following an investigation by the Medical Service Subcommittee. While the committee had a discretion to make a representation in this particular way, he considered the powers given in Part VI. Articles 41 and 42 (regarding the making of representations and the holding of inquiries) were general and that representations could be made, as had been done in the case of these doctors. In their case, after the Medical Service Subcommittee had reported, the Minister had recommended the Insurance Committee to proceed by representation under Part VI. This had had as its result the decision to deduct by instalments the sum of £1000, and in his view the action of the Minister was not *ultra vires*. Mr. Justice Roche and Mr. Justice Branson concurred, the latter stating, as regards the position of Dr. C. D., that he was a panel practitioner and his terms of service were that he should not take private fees from panel patients.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following table gives some of the principal health statistics for 1923 of one county borough, six boroughs, and one urban district, the health reports of which are commented on below :—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Eastbourne C.B.	53,900	13·3	9·7	0·9	1·3	1·4	25	39	†
Ramsgate B. .	30,250	20·7	12·9	1·1	1·5	1·7	19	45	0·0
Margate B. . .	28,080	17·3	10·6	1·3	1·6	1·0	†	43	6·2

* Gillingham's population for the calculation of death-rates is 47,620.

† Indicates that the information is not given in the report.

Eastbourne.

Dr. W. G. Willoughby reports that housing is still the most adverse factor in this county borough and that the outlook is only very gradually improving. However much one may theoretically believe in private ownership, he says, there is no alternative to State housing if private owners refuse to let houses to families with young children. Such an attitude on the part of private owners is common in Eastbourne. For the municipal houses, on the other hand, preference is given to large families. Dr. Willoughby considers that about 700 new houses would meet present requirements. The houses completed during 1923 numbered 102, of which 30 were municipal houses. All the municipal houses have baths, and the rents are 18*s.* 4*d.* per week for parlour houses and 14*s.* 8*d.* for non-parlour houses. Reference is made to the hopeless state of the law as regards milk which does not come up to the standard of 3 per cent. for fat and 8·5 per cent. for non-fatty solids. The only two prosecutions undertaken failed. Some of the special difficulties of the tuberculosis scheme are the want of satisfactory housing accommodation, of hospital provision for surgical tuberculosis, and of suitable employment for tuberculous persons who can do a little work. The municipal maternity and infants' home did useful work; 17·6 per cent. of all the births in the borough took place there and 32 ailing infants were admitted in addition to those born in the home. Considerable trouble has been experienced with regard to unqualified women acting as midwives, and the proviso in the Act as to "habitually" and "for gain" makes legal action difficult.

In his school report Dr. Willoughby says it is too early to speak as to the effect of the introduction of the system of charging for treatment, but he is glad the board have allowed them some latitude in the application of the new regulations. Permission to establish a massage and electrical clinic was refused, but fortunately the work has been carried on at a voluntary clinic. The reduction of uncleanliness and verminous conditions in the schools is marked in recent years. There are many refusals to accept dental treatment. The open-air school, formed out of army huts and opened in June, 1920, has fully justified its existence, and its accommodation has been increased to 75 places. Medical inspection of the 658 children in the two municipal secondary schools showed that 272 required treatment or observation. For the majority of these the parents were asked to provide medical attention, but 33 were treated free at the school clinics. Dr. E. H. Coghill reports that among the girls the outstanding defects were enlarged tonsils and enlarged cervical glands, probably arising from tonsils and teeth. The general physique was good and cases of spinal curvature few. As regards the boys, Dr. T. Turner reports a gratifying reduction in flat-feet, which he attributes to the disappearance of the effects of poor feeding during the war. Enlarged tonsils and adenoids are now negligible, owing to treatment, breathing exercises, &c., during the earlier school period. Dental caries is, however, much too common.

Ramsgate.

Dr. W. J. Bannister also says that housing is still the most pressing problem, and that the only hope for an adequate provision of small houses lies in a State or municipal scheme. No municipal houses were erected in 1923. Two of the 121 cows housed in the borough were found to be suffering from generalised tuberculosis and were destroyed at the knacker's yard. Most of the meat sold is imported foreign meat. Efficient supervision of the meat killed in the borough is not possible owing to the situation of the various private slaughter-houses and the fact that killing goes on at all hours. On the other hand, the butchers have an insurance scheme against condemnation, which encourages the notification of suspicious meat to the health department. The council's station for the sterilisation of shell-fish dealt with 34,614 gallons of cockles during the year. The premises on which ice-cream was made and stored were reported to be satisfactorily kept. The school report shows that seven of the nine elementary schools are non-provided and do not comply with modern sanitary requirements. Six prosecutions of parents were undertaken for uncleanliness of their children. Many of the children, found to be in a pre-tuberculous condition, have to be excluded from school for long periods, in the absence of an open-air school. During the year 152 children were found to have enlargement of tonsils or adenoids. In most cases the condition yielded to attention to carious teeth, &c.; only 14 cases received operative treatment. The school dentist, Mr. P. H. Hickman, reports that many parents refuse treatment for their children. No organiser of physical training for the area has been appointed, although Dr. Bannister reports strongly in favour of such an arrangement.

Margate.

Dr. Rowan McCombe refers—the reference is cumulative—to the handicap to the standard of health and cleanliness resulting from the deplorable shortage of houses. In 1923, 22 municipal houses were built, but 300 are needed immediately. In the older parts of the town not only cottages but also better-class houses have no bathrooms, and the provision of public baths is greatly needed. Of the four midwives practising in the town, two are municipal and occupy their spare time in antenatal visiting. In his school report Dr. McCombe reports that uncleanliness has been more prevalent among the school-children during 1923. He would like to have some more prompt and direct method of dealing with apathetic parents, such as power to cut the hair short or making it an offence to send children to school with verminous heads or bodies. Dr. McCombe would also like to see an open-air school established to accommodate 20 to 30 children.

Hendon.

"Happy Hendon" had, Dr. T. S. McIntosh tells us, no public health history in 1923. A scheme is in course of preparation for the coördination and extension of the child welfare and school medical services, and more supervision is needed of children between the ages of 2 and 5. Hendon is apparently unique among urban districts in having no housing problem. The number of houses erected during 1923 was 625, of which 20 were municipal. One closing and demolition order was carried out, and at the end of the year there were no houses unfit for habitation.

Gillingham.

Dr. W. A. Muir reports that the isolation hospital is unsuitable for its purpose and its site too small. Suitable sites for a modern hospital have been offered, and it is suggested as an alternative that the borough might join with the neighbouring boroughs of Chatham and Rochester. Like the medical officers of many large urban districts, Dr. Muir thinks the supervision of midwives should be transferred from the county council and form part of the Gillingham maternity and child welfare scheme. Two firms in Gillingham now sell wrapped bread and the hospital committee are among their customers. The chief sanitary inspector attended the demonstration of methods of slaughtering arranged by the National Federation of Meat Traders' Associations. Dr. Muir refers to the view of the Federation that the humane killer interferes with the keeping properties of the meat, more especially of pig's flesh, with regard to which investigation is still taking place. There is still a marked shortage of houses, but no municipal houses were built during the year. About £15,000 was advanced during the year ended March 31st, 1924, to enable tenants to acquire the ownership of their houses under the Small Dwellings Acquisition Act, 1899.

Watford.

Dr. W. J. Cox prefaces his report on housing by extracts from a speech delivered by the King at a housing reception held at Buckingham Palace on April 11th, 1919. Since then nearly 1000 municipal houses have been erected, but 1000 more are needed. There are about 300 houses unfit for habitation, many of them in an extreme state of disrepair and some indescribably filthy and infested with rats and other vermin. The Infants' Home at Little Nascott, which was originally started as a war creche, is now serving a useful purpose as a home for the reception of delicate and ailing babies, 44 of 77 admissions during the year being of that type. A dental clinic has been begun for nursing and expectant mothers, and children under school age. The Watford special school for mentally defective children (accommodation 40) continues to do good work.

Hyde.

Dr. Nicolas Gebbie, like his colleagues, refers to the shortage of houses and overcrowding. His references to the smoke problem leave the impression that practically no action is being taken with regard to mill and factory chimneys. He states that the smoke problem "is in large measure a problem of the household chimney." A glance at the statistical table above tempts one to suggest that industrial smoke may be one reason why the death-rate from respiratory diseases in Hyde is nearly three times that of the other towns and that industrial smoke may be worth while tackling, whilst the public is being slowly educated in the matter of the domestic use of coal. In his report on the maternity and child welfare work Dr. Gebbie refers to the high neonatal mortality, and says the antenatal branch of the work does not increase like the rest of the work and that, so far, only a few of the midwives have availed themselves of the invitation to bring or send cases to the antenatal clinic. The school dentist, Mr. E. A. P. Parker, reports that of the children selected for treatment about 78 per cent. avail themselves of the opportunity.

Stafford.

Dr. J. T. Macnab says housing difficulties continue to be acute but that fresh activity is being shown, and it is hoped that the current year will bring some relief. Dr. Macnab advocates the protection of children during their school career against diphtheria by the administration of the two or three necessary injections of toxin-antitoxin. This offer is now made to parents in Stafford. Referring to the high neonatal mortality and the crowding at the infant welfare centres, Dr. Macnab mentions that sanction has been asked to the appointment of a second health visitor in order to enable antenatal work to be done and the holding of more sessions at the centre. A duplicate water main from Milford was brought into use early in the year, so that the supply of the town is now protected against accidental stoppage. Cesspits and privies will be abolished as the result of the completion of the new sewers at Rising Brook and Doxey. Waste-water closets cause much trouble by becoming blocked, the liability to stoppage being about eight times that of the pedestal w.c. with flushing cistern.

SCHOOL MEDICAL SERVICE.

Glasgow.

IN Scotland the school year now ends on July 31st and the medical officer's statement is incorporated in the Director of Education's annual report. It is difficult from this rather brief statement to get an adequate idea of the enormous amount of good work, much of it pioneer, which we know is going on in Glasgow. The total number of children for whom the education authority is responsible is 194,267, of whom 790 are under 5 years of age and 1134 over 14. Thirteen hostels are in operation for children whose parents have to leave them during the day. In seven cases nursery sections are attached for children from 2 to 5 years of age. These children are looked after by women appointed for the purpose, while in the larger nursery schools teachers are in charge. During the year 32,639 children came under routine medical inspection, and of these 45·2 per cent. were found with defects. There are six principal and 12 subsidiary clinics, with, in addition, two special clinics for tonsil and adenoid operations and ringworm and favus cases. The treatment of chronic otorrhœa by zinc ionisation has been extended, and during the year 152 of these cases were dealt with. The statistics regarding treatment show a considerable increase in cases generally, which is in part attributed by Dr. E. T. Roberts to the industrial depression. There was an increase of 17 per cent. in ear cases, 6 per cent. in eye cases, 10 per cent. in skin disease, and 24 per cent. in other diseases. The large increase of 44 per cent. in the number of cases of chronic suppuration of the middle ear was possibly due to the severe epidemic of measles which occurred in the first half of 1922.

From a survey of heights and weights for the five pre-war and four post-war years it appears that war-time conditions have resulted in a slightly improved physique among the children. There is a post-war increase in 13 of the 16 averages given. At the same time the lowered state of health found among the children for 1922 is continued into 1923. During one month of the winter of 1922 four mild cases of sore throat made their appearance in the Langside Deaf and Dumb Institution. Bacteriological examination revealed these as cases of diphtheria. Swabs of 130 children and 43 members of the staff were taken, and 35 positive or potential carriers discovered. These were kept under strict supervision until bacteriologically negative, and a Schick test was carried out with the consent of the parents on 115 pupils and on 35 consenting members of the staff. The results were positive in 36 cases. All susceptible pupils were immunised against the disease, and as a result of such prompt and thorough methods no further cases occurred in the institution.

Radcliffe.

Dr. John Gibson deplores the uncleanly state of the Radcliffe schools, and points out what his predecessor, the late Dr. D. P. M. Farquharson, reiterated time after time: "If a child is brought up in a dirty, overcrowded home and attends a school where no one seems to care if the floor and windows are dirty and dust is seldom disturbed, then that child will in later life be quite content with a low standard of cleanliness." He suggests that the children might assist in the cleansing of their classrooms. The remedy proposed is distinctly a debatable one, but something ought to be done to remedy conditions where, as was pointed out in 1921, "dust lies thick on every place where it can find a lodgment." The outside sanitary arrangements here are evidently good, but the administration is bad; at some of the schools where the trough system of closets is in use they are flushed but once a week. Flushing twice a day should be the rule laid down for every school. During the year there were 2924 attendances at the dental clinic, the number of scalings and cleaning being 309. The school dentist, explaining this apparently large proportion, says that even though the use of the tooth-brush is unknown in many homes, he very much doubts its efficacy in the prevention of dental caries. Out of a school roll of between 3000 and 4000 considerably more than half were medically examined. By an arrangement with the school attendance officers all children absent from school on account of sickness are at once notified to the medical officer and are visited by the school nurse. This is considered one of the most important duties of the nurse. There are two nurses employed, at salaries of £181 and £166 10*s*. (including bonus).

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 31ST, 1924.

Notifications.—The following cases of infectious disease were notified during the week—namely, small-pox, 75 (as against 101 the previous week); scarlet fever, 1450; diphtheria, 788; enteric fever, 88; pneumonia, 900; puerperal fever, 45; cerebro-spinal fever, 14; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 251 (as against 261 the previous week); trench fever, 1; dysentery, 9; ophthalmia neonatorum, 150. There were no cases of cholera, plague, or typhus fever notified during the week. Of the 14 cases of cerebro-spinal fever 6 were notified from the County of London (Bermondsey 1, Hackney 2, St. Pancras 1, Shoreditch 1, Woolwich 1), 2 from Durham (Sunderland), and 1 each from Cumberland (Carlisle), Lancaster (Liverpool), Northampton (Wellingborough), Somerset (Weston-super-Mare), Surrey (Wimbledon), and Yorks, W. Riding (Bradford). Of the cases of encephalitis lethargica 23 were notified from the county of Durham (Sunderland 9, West Hartlepool 1, Felling U.D. 1, Hebburn 2, Ryton 1, Spennymoor 2, Auckland R.D. 1, Chester-le-Street R.D. 1, Easington R.D. 1, Sedgefield R.D. 2, Sunderland R.D. 2), 24 from Lancaster (Liverpool 8, Manchester 4), 23 from Warwick (Birmingham 16), and 27 from Yorks, W. Riding (Sheffield 10).

Deaths.—In the aggregate of great towns the deaths from influenza fell further from 67 to 52. There were in London 9 deaths from diphtheria, 12 only from measles.

FOREIGN DECORATIONS.—The King has given to Mr. Douglas Erith Derry, M.B., Ch.B. Edin., licence and authority to wear the Decoration of the Order of the Nile (Insignia of the Third Class), which has been conferred upon him by the King of Egypt in recognition of valuable services rendered.

THE GENERAL MEDICAL COUNCIL.

(Concluded from p. 1173.)

Penal Cases.

THREE penal cases came before the Council on the last day of the May session.

The first was brought by the Medical Defence Union against a practitioner on the following charge :

> "That, being a registered medical practitioner, you have employed as your assistant in connexion with your practice, one—namely, ————, not duly qualified or registered under the Medical Acts, and have knowingly allowed him on your behalf to attend and treat patients in matters requiring professional discretion or skill ; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

After deliberation the President announced that the Council had decided to dismiss the case, but thanked the complainants, as on prima facie evidence they had a reasonable case.

The second case was brought before the Council by the Dental Board. A registered medical practitioner was charged with giving a written testimonial to an unqualified dentist stating that "you believed he had a perfectly good reputation" and that "you considered him quite suitable for inclusion in the Dentists Register," whereas the dentist was not personally known to him, nor did he know anything of his moral character. The Council warned the practitioner and did not see fit to erase his name from the Register.

The Case of Dr. Frederick John Fehrsen.—The Cape Medical Council referred to the General Medical Council the case of Frederick John Fehrsen, registered as of Sea Point, Cape Town, M.B., C.M., 1879, M.D., 1884, U. Aberd., who had been summoned to appear before the Council on the following charge :—

> "That, being a registered medical practitioner, you wrongfully, unlawfully, and with intent to procure the miscarriage of one Martha de Lange, performed certain operations upon her, and thereby wrongfully, unlawfully, and wilfully procured her miscarriage, of which offence you were on Nov. 13th, 1922, convicted after trial by jury in the Supreme Court of South Africa at Grahamstown, Cape of Good Hope, and in respect of which offence you have been since judged by the Colonial Medical Council of South Africa to have been guilty of infamous and disgraceful conduct, and your name has been erased from the Register of Medical Practitioners of the Province of the Cape of Good Hope ; and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The Council directed the Registrar to erase the name of Frederick John Fehrsen from the Medical Register.

In regard to the case of Henry Love, mentioned in THE LANCET last week, the facts alleged against him in the notice of inquiry having been proved, an opportunity was given to him of reconsidering his position, judgment being postponed until May, 1925.

DENTAL BOARD OF THE UNITED KINGDOM.

FINAL SITTING OF THE FIRST BOARD, MAY 13TH–16TH.

THE final sitting of the first Dental Board was held from May 13th to 16th, and we have already summarised the opening address[1] of the Chairman, Mr. Francis Dyke Acland. The other members of the Board who attended the sitting were Mr. L. G. Brock, Mr. W. H. Dolamore and Mr. W. H. Gilmour (nominated by the Ministry of Health), Mr. D. M'C. Cowan and Mr. W. Guy (Scottish Board), Mr. J. H. Stirling and Mr. E. L. Sheridan (Lord Lieutenant of Ireland), Mr. H. J. Waring, Sir James Hodsdon and Sir Arthur Chance (General Medical Council), Mr. F. Butterfield and Mr. H. A. Robertshaw (Privy Council).

Penal Cases.

Eight disciplinary cases were the subject of consideration. The first case, that of a dentist, 1921, charged with making a false statutory declaration in regard to the employment of an assistant, was dismissed as not proven. In the second case an L.D.S. convicted of indecent exposure was put on probation until the November sitting. In the third, a dentist in practice on July 22nd, 1878, was charged with advertisement on the cover of an almanack, and with improper use of the letters "R.D.S." The facts alleged being proved, an assurance was accepted not to transgress again. In the fourth case, a dentist, 1921, in addition to obtaining goods on false pretences, was shown to have gained access to the Register on a faulty declaration, and his name was erased on this ground. In the fifth case, a dentist, 1921, proved to have aided and abetted his unregistered son to practise dentistry, and to have permitted him to practise in his father's name, was recommended for erasure. In the sixth case, an L.D.S. was proved to have used advertisements on windows, swing signs, and brass plates, in size and quantity greatly in excess of anything required for legitimate professional purposes. The facts alleged having being proved, he was put on probation until November. In the seventh case, a body corporate carrying on the business of dentistry was shown to have advertised, with a view to procuring patients, by means of electric lamps, projecting signs, plates, and boards of a character, size, and wording more than reasonably required to indicate the exact location of the premises. In order not to tie the hands of the new Board judgment was deferred until the next session. In the last case a dentist, 1921, proved to have advertised, with a view to procuring patients, by means of a board 12 feet in length, three electric light-globes painted red, swing signs, show-cases, and other means, was given until November to reconsider his position.

Reciprocity.

A copy of the Dentists Act, 1923, of Barbados was received from the Privy Council, providing that any qualification entitling to registration in the United Kingdom after a course of not less than four years should be recognised for insertion on the Barbados Register. This Act further forbids an unregistered person to practise or do any dental operation for a fee under a penalty of £20 or two months' imprisonment.

Appointment of Committees.

The following Committees were instituted, namely :—

Business Committee : Mr. Brock (Chairman), Mr. Dolamore.

Discipline Committee : The Chairman, Mr. Butterfield, Mr. Gilmour, Sir James Hodsdon, Sir Arthur Chance, Mr. Sheridan.

Educational Grants Committee : Mr. Brock (Chairman), Mr. Robertshaw, Mr. Waring, Mr. Cowan, Mr. Guy, Mr. Sheridan.

Examination Committee : Sir James Hodsdon (Chairman), Mr. Dolamore, Mr. Robertshaw, Mr. Guy, Mr. Sheridan.

Finance Committee : Mr. Waring (Chairman), Mr. Brock, Mr. Dolamore, Sir James Hodsdon, Mr. Stirling.

Registration Committee : The Chairman, Mr. Butterfield, Mr. Gilmour, Mr. Robertshaw, Mr. Cowan, Mr. Stirling.

Research Committee : Mr. Dolamore (Chairman), Mr. Brock, Mr. Gilmour, Mr. Guy, Mr. Sheridan.

The completion was reported of the seal of the Dental Board by Mr. Lessor, which would in future be attached to the formal documents of the Board.

Educational Grants Committee.

It was reported that the Dental School at Belfast had qualified for the grant of £2000 ; the Edinburgh Dental Hospital for £6000 ; the Liverpool Dental School for £2400. Birmingham Dental School intimated that for financial reasons the grant of £1500 could not be taken advantage of at present. The decision of Leeds Dental School, where the staff have undertaken to subscribe £2000, was postponed. King's College grant of £700 will be paid against receipts for new equipment. No decision as to grant had been received from the London Hospital Dental School or the National Dental Hospital.

---

[1] THE LANCET, May 24th, p. 1066.

Decision as to the grant of £900 to the Incorporated Dental Hospital of Ireland was adjourned in view of the doubt whether the Free State is now within the jurisdiction of the Dental Board.

The number of students assisted by educational grants or loans up to March 31st, 1924, was 145, of whom 73 had obtained their diploma, 43 were still being assisted, 17 were continuing at their own expense. Of 104 students assisted after the expiration of the Government grants 68 had been enabled to qualify. Of five students in receipt of loans who had qualified one had already commenced repayment by instalments.

Examination Committee.

The fifth and sixth series of prescribed examinations were held in December, 1923, and April, 1924. The December examinations furnished the first opportunity of presenting themselves to persons entered on the list of candidates under the Dentists Act, 1923. At the December examinations there were 28 of these and 53 at the April examinations. There is a total of 633 names on the list of candidates intending to pass the prescribed examinations—namely, 542 dental mechanics, 40 war service candidates, 51 practitioners of 21 years of age.

Attendance at the post-graduate lectures had not been very encouraging, but it was hoped that the institution of a local list of persons on the Dentists Register would enable notices to be sent in future to all dentists resident in the neighbourhood. The average attendances had been, to take one or two examples: Bristol 40, Birmingham 25, Manchester 30, Edinburgh 50. The arrangements for courses of lectures in connexion with the post-registration study, on the other hand, were reported an unqualified success, and there was a general wish that the courses should be repeated next winter, the syllabus to include more practical work and demonstrations with actual patients. The average attendances had been, e.g., Leeds 29, Newcastle 37, Glasgow 65. It was resolved to arrange lectures in the coming session at Birmingham, Cambridge, Cardiff, Manchester, Nottingham, and, if the Board was competent to do so, at Dublin.

Propaganda Committee.

The Board undertook, at the suggestion of the British Broadcasting Company, to provide a lecturer to give one or two talks on dental matters, to be inserted in a programme of talks on other governing factors in public health. The Board of Education was to be invited to receive a deputation from the Board with reference to the institution of suitable instruction in oral hygiene in primary and secondary schools. When the Royal Commission on the National Insurance Acts has been appointed, the Board desires to give evidence as to the need of extending the present provision of dental treatment under the Acts. Authority was given for initial expenditure of a sum not exceeding £50 on the purchase of films bearing on dental subjects for propaganda purposes.

Research Committee.

A confidential report on dental alloys and amalgams was received from Dr. W. Rosenhain, F.R.S., and Prof. E. E. Glynn was granted a sum of £300 to pursue research on the relation between dental sepsis and blood-sugar tolerance, glycosuria, and diabetes.

Free Choice of Dentists.

A memorandum received from the Public Dental Services Association in regard to a circular of the Ministry of Health contained a sentence to the effect that approved societies "do not in all cases allow their members free choice of a dentist." The Board had already written to the Ministry to point out its view that patients had a right to select their own dentists, and that if pressure was put upon patients to seek advice from certain individuals, the practitioners associated with the canvassing body would come under the warning resolution in regard to advertising and canvassing. The Board's view was that if all dentists in a neighbourhood who desired to do so were permitted to enter into arrangements with approved societies, without advertisement of their names, no exception should be taken. Subsequently a letter was received from the Ministry of Health, stating that an approved society would not be entitled out of State Insurance funds to set up and maintain a clinic for dental work, although the case was different for a clinic established by a charitable organisation. The Ministry, however, was considering whether it might not be compelled to give a definite ruling on the extent to which departure from absolute freedom of choice of dentist could be allowed. The letter added that the Ministry hoped to get dental benefit on much better and more systematic lines after the second valuation now proceeding.

At the conclusion of the business Mr. Norman King was reappointed Registrar until Dec. 31st, 1924, and the best thanks of the Board were given to the Chairman for his able services during the present session.

Obituary.

ROBERT KENNEDY, M.A., D.Sc., M.D. Glasg., F.R.F.P.S. Glasg.

By the death of Robert Kennedy, St. Mungo professor of surgery at Glasgow, the city and University have lost one of their most distinguished professors and science a keen investigator. The loss is the greater as it follows so closely upon the death of other renowned Glasgow surgeons, notably Mr. James H. Nicol, Sir Kennedy Dalziel, and Sir William Macewen.

Robert Kennedy was born in Glasgow in 1865, and received his early education at the High School. He proceeded to Glasgow University, where in 1887 he graduated B.Sc., and the following year M.A. with first-class honours in natural science. In 1889 he became a Doctor of Science, and in 1890 qualified M.B., C.M. with commendation. He took the M.D. with honours, and in 1921 he was admitted F.R.F.P.S. of Glasgow. As a student he won the John Clarke and George A. Clarke scholarship in open competition. Previous to graduation in medicine he was assistant in zoology to the late Prof. John Young, and in botany to Prof. Bower. He also held the post of lecturer in embryology in the University of Glasgow under the Clarke foundation, and lecturer in biology in the Glasgow and West of Scotland Technical College.

In 1890, after graduation, he studied for over a year in the University of Berlin under many of the best known teachers, notably Virchow, Koch, von Bergmann, Olshausen, and Leyden. His study of bacteriology under Koch had, in consequence of the work of Lord Lister, become a necessary preparatory training to the practice of antiseptic and later aseptic surgery. On his return to Glasgow Prof. Kennedy held many important surgical posts. From 1892–96 he was surgeon to out-patients in the Victoria Infirmary until appointed to the surgical staff of the Western Infirmary, where he eventually became visiting surgeon. In the Western Infirmary he was assistant to the late Dr. Patterson for ten years, and was at the same time assistant surgeon in the lock hospital and examiner in surgery at the University of St. Andrews.

In 1906 Kennedy was appointed lecturer in applied anatomy by the Glasgow University Court, and in 1911 the curators of the St. Mungo Chair of Surgery in the University selected him as its first occupant. This selection was inevitable in view of his extensive research in many directions, notably in the surgery of the nervous system. These researches were accepted by the Royal Society of London for publication in their Philosophical Transactions. In 1903 Kennedy's researches were considered of such importance by the French School of Surgery that a translation of them was published in "Chipault's l'Etat actuel de la Chirurgie Nerveuse." His work included many experiments on the restoration of paralysed muscle by means of nerve anastomosis, and on the restoration of coördinated movements after nerve-crossing with interchange of function of the cerebral cortical centres. He performed extensive investigations into nerve regeneration, and the restoration of coördinated movements after nerve section. Kennedy was a prolific writer; many of his papers were included in the Transactions of the Royal Society of Edinburgh, the Royal Philosophical Society of Glasgow, and in many other medical publications.

Lord Lister, referring to Kennedy's investigations into the regeneration of nerves, said: "The subject is of the highest scientific interest and of very great surgical importance, and it has consequently claimed the attention of distinguished investigators for many years past. It nevertheless remained involved in great obscurity till Dr. Kennedy, availing himself of favourable opportunities which occurred to him as a surgeon, so combined acuteness of observation with sound discriminating judgment as to solve completely, as it appears to me, the difficult problem." Dr. M. Bernhardt, professor of neurology in the University of Berlin, regarded Prof. Kennedy as one of several savants who must be specially reckoned in contributions to the nervous system, and he included Kennedy's work in his book, "Die Erkrankungen der Peripherischen Nerven."

Among his many other researches Kennedy introduced the operative treatment of birth paralysis of the arm, a new method of operation for the radical cure of inguinal hernia, a method for the radical cure of varicose veins, treatment of cicatricial deformities of the hand, exposure of nerves for operations for wry-neck, &c. During the war Prof. Kennedy, as surgeon-in-chief of the Shakespeare Hospital, and later of Bellahouston Hospital in the Ministry of Pensions, did invaluable work among the wounded, involving many hundreds of major surgical operations, including numerous cases of removal of bullets and foreign bodies from the brain.

But for his sudden and unexpected death he would have journeyed this year to Canada as a delegate to the British Association meeting at Toronto. The loss of his son and wife at so short an interval came as a severe blow to him, and no doubt hastened the end. Every sympathy is extended to his only daughter in her great loss.

His friend, Sir J. S. S., sends the following appreciation: "Prof. Kennedy enjoyed the friendship of a wide circle, and was closely identified with the literary life of Glasgow. He took the deepest interest in the abortive movement for the preservation of the Lister Ward in the Royal Infirmary, and was ever at the disposal of his professional brethren, and freely gave them the benefit of his unique experience. He was essentially a scientific surgeon, and he was constantly adding to his knowledge by keeping in touch with other schools and the methods of other specialists at home and abroad. He was intolerant of slip-shod methods, and followed personally the progress of each case, whether it occurred in the public wards of the Royal Infirmary or among his private patients. He disguised under a somewhat brusque exterior a tender and sympathetic heart, and his loss will be mourned by a countless number of patients who came to look upon him as a friend."

DONATIONS AND BEQUESTS.—By the will of the late Mr. Emil Teichmann, of Chislehurst, the testator left among other bequests £2000 to St. Bartholomew's Hospital "in remembrance of my son Oskar's student days"; £500 to the National Institute for the Blind; and £500 to the Chislehurst, Sidcup, and Cray Valley Cottage Hospital.—The late Mr. Frederick Shiers Smith, of Skipton, left by will £500 to the Skipton and District Hospital; £500 to the Leeds Infirmary; £500 for distribution between the Cancer Hospital, Fulham-road, the Middlesex Hospital Cancer Charity, the Gordon Hospital, Vauxhall Bridge-road, and St. Mark's Hospital, City-road.—By will the late Mr. Thomas Murphy, of Chesterfield, among other bequests left £10,000 to the Chesterfield Royal Hospital for a "Murphy Ward," with all necessary provision of staff and other accommodation.

SPINAL-CORD LESIONS IN PEMPHIGUS VULGARIS.

To the Editor of THE LANCET.

SIR,—I have recently examined portions of the central nervous system obtained from a fatal case of pemphigus vulgaris and have found definite pathological changes in the spinal cord. The changes were chiefly those of an invasion of the central canal with mononuclear cells which morphologically resembled fibroblasts. The central canal was presumably occluded in its whole length as the lesions were present to the same extent in all the sections of the cord examined. A few small hæmorrhages were found in the substance of the cord with a slight amount of perivascular, lymphocytic infiltration. No definite lesions were found in the other parts of the central nervous system examined. Efforts to transmit the disease to animals have, up to the present, not met with success, but the material used for the inoculations was glycerinated as no special precautions had been taken to collect it in a sterile manner. One animal only showed a transient weakness of one of the fore-limbs, and appeared to be ill for a few days; recovery seems, however, to have been complete.

I am, Sir, yours faithfully,
C. C. TWORT, M.D. Aberd.

Pathological Dept., St. Bartholomew's Hospital,

"INDUCTION" OR "CAUSE" OF CANCER.

To the Editor of THE LANCET.

SIR,—Sir Lenthal Cheatle is grieved because some of us have failed to realise that "the factors that induce carcinoma belong to quite a different category from those that cause it." He repeats this four times, in different words, in the course of his short letter. What we have said is that the agents with which we have induced cancer experimentally are the prime, proximate, or inciting causal agents as distinguished from secondary, mediate, or contributory causes, as far as the particular results are concerned. If we have sinned in confusing the words "induce" and "cause" we have done so in goodly company. Webster's dictionary, for example, gives as one of the meanings of "induce" "to cause."

If Sir Lenthal Cheatle, for whom and for whose contributions to the study of cancer I have a profound respect, would be so good as to give us half a dozen examples of diseases that can be *induced* by something which does not *cause* them, I will truly seek repentance and renounce my allegiance to the lexicographers.

I am, Sir, yours faithfully,
ARCHIBALD LEITCH.

The Cancer Hospital Research Institute, Fulham-road,
London, S.W. 3, June 7th, 1924.

TOXIC EFFECTS OF LOCAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—If Dr. P. Watson-Williams will turn again to my letter he will see that my reference to the advisability of always combining adrenalin with cocaine is preceded by the words: "It may, I think," whereby I intended to convey the impression that it was a suggestion I was making, rather than a rigid generalisation, the perils of which I am well aware of. For the point is, I know, one for debate. No one will, perhaps, quarrel with the dictum that, as a rule, and particularly in extensive anæsthetisations, adrenalin should always accompany cocaine. In the matter of light anæsthesia of the nose, however, as for examination purposes, the question is, as Dr. Watson-Williams quite correctly implies, not by any means so simple. In light sprays, adrenalin frequently sets up an annoying reaction, with sneezing and running at the nose, which I have known to last as long as 48 hours, and to be a cause of much bad language, directed, and with perfect justice, to the rhinologist's address. But, on the other hand, I have occasionally seen cocaine syncope follow even a trivial spraying of the nose with pure cocaine solution; the drug is then so rapidly and completely absorbed.

So there the problem stands, and each man must solve it for himself. Personally, I prefer a swearing patient to a fainting patient. But I am quite ready to admit that others may cherish the opposite opinion. May I add that syringing the nose with warm saline solution after adrenalin-cocaine spraying can, as a rule, but not always, be relied upon to avert any subsequent irritation. It is curious that so violent a reaction seldom follows the more continued anæsthetic applications needed for operation.

I am, Sir, yours faithfully,

Dan McKenzie.

GASTRIC AND DUODENAL HÆMORRHAGE.

To the Editor of The Lancet.

Sir,—Dr. A. C. Jordan's comments on Dr. A. F. Hurst's valuable communication on this subject merit a passing comment. Dr. Jordan's commentary on the relationship of gastric and duodenal disorder to primary disease in the ileo-cæcal region is, in my opinion, well founded, as is also his recommendation in regard to the use of enemata as an essential part of the treatment. Perhaps one reason why progress is made so slowly in unravelling the mystery of disease is the present classification of disease and the too restricted outlook arising from it. It is, I think, doubtful whether simple gastric or duodenal ulcer ever occur as primary conditions. Apart from the measures which are necessary in an emergency, treatment should be mainly directed to the primary defect in the ileo-cæcal region and colon. If the suggestions as to ætiology and treatment in Dr. Hurst's communication are considered along with the facts brought out in Dr. Jordan's letter, and investigations made continually by the light of that teaching, our knowledge of the ætiology and treatment of gastric and duodenal ulcers would, before long, be on a much higher plane than at the present time.

I am, Sir, yours faithfully,

Chalmers Watson, M.D.

Edinburgh, June 6th, 1924.

THE PSYCHOLOGY OF SEA-SICKNESS.

To the Editor of The Lancet.

Sir,—May I answer the questions of F.R.C.S. in your issue of May 31st in reverse order? In my opinion sea-sickness is always of psychical origin and this appears to be a widely accepted impression, seeing that all medicines recommended for the malady come under the category of nervous sedatives, while other remedies, such as looking in a mirror, are obviously for the purpose of auto-suggestion. I am fortunately able to answer his other question from psycho-analytical experience of patients. Even exclusively artificial feeding does not necessarily render a child immune from sea-sickness. One of my patients (an obsessional case), who is still undergoing psycho-analysis, chanced to work through a phantasy of feeding in his mother's arms and thus incidentally cured himself from being a very bad sailor indeed; yet he knew from information received that he had been "brought up on the bottle." He explained that he might well be nursed against his mother's breast while feeding from a bottle.

The situation is, however, not quite so simple. The essential factor for the development of excessive oral libido is over-stimulation of the mouth during infancy, perhaps by "dummies," the nurse's finger, and the child's own thumb, as well as the mother's breast; while the associated rhythmical respiratory heaving motion during feeding is too often supplemented or replaced by jigging the child to and fro or up and down, cradle-rocking, swinging, and so forth. The fact that F.R.C.S. and his son are good sailors may probably be ascribed to their nurses refraining from undue oral stimulation, or from abnormal rocking movements, or both.

I hope that it is unnecessary to add that this explanation of sea-sickness will never cure a patient suffering from it. To be effective, he must discover the explanation for himself, out of his own mind. Otherwise he will simply refuse to believe it, as indeed will most of your readers unfamiliar with psycho-analytical investigations.

I am, Sir, yours faithfully,

W. H. B. Stoddart.

Cavendish-square, W., June 6th, 1924.

ROCKEFELLER ENDOWMENTS AT HONG-KONG.

To the Editor of The Lancet.

Sir,—In your issue of March 1st (p. 465) it is stated that the Rockefeller Foundation allocated the sum of $250,000 to the Hong-Kong University for the chairs of medicine and surgery. Will you permit me to make the following corrections? On May 24th, 1922, the Foundation appropriated the sum of $500,000 for the endowment of the chairs of medicine and surgery. More recently, on Feb. 5th, 1924, the Rockefeller Foundation generously appropriated a further sum of $250,000 for a chair of obstetrics and gynæcology. The Hong-Kong University was founded in March, 1911, and opened in 1912 as a residential University for students of both sexes of all races, nationalities, and creeds, not as stated in your note for British subjects only.

I am, Sir, yours faithfully,

Kenelm H. Digby,

Dean, Faculty of Medicine, University of Hong-Kong.

April 23rd, 1924.

THE KASR-EL-AINY HOSPITAL AT CAIRO.

To the Editor of The Lancet.

Sir,—You are, I believe, wrong in thinking that the King of Egypt has opposed the project of building a new hospital and centre of medical education in Cairo. King Foad has always encouraged anything likely to benefit his country. The project has been discarded for the present by the advice of a special committee held to report on that subject. It may please you to learn that the King of Egypt has recently ordered the purchase of a tuberculosis sanatorium of 360 beds at Helouan, originally built by Baron Kioppe on the most modern lines. This sanatorium will shortly be ready to receive patients, pulmonary and otherwise, who will have an exceptional opportunity of cure or relief by heliotherapy.

I am, Sir, yours faithfully,

Cambridge, June 6th, 1924. I. Yousry, M.D.

DOMINIONS MEDICAL HOSPITALITY.

To the Editor of The Lancet.

Sir,—You printed last week a programme of the arrangements made by my committee for the entertainment of overseas visitors. Certain forms have been returned to me unsigned, making it impossible to comply with the wishes expressed on them. May I through your columns appeal for the names and addresses of the writers?

I am, Sir, yours faithfully,

A. E. Mortimer Woolf,

Hon. Secretary, Dominions Medical Hospitality Committee.

94, Harley-street, London, W., June 10th, 1924.

LEAD AND CANCER.

To the Editor of THE LANCET.

SIR,—The annotation under the above title on p. 1164 in your issue of June 7th, dealing with Prof. Blair Bell's address which appears in the current issue of *Public Health*, induces me to draw attention to the following information drawn from Table V. of the Supplement to the Seventy-Fifth Annual Report of the Registrar-General, Part 4.

Comparative Mortality Figures.

Group.	1910–12.		1900–02.	
	Cancer.	Lead.	Cancer.	Lead.
Lead manufacturers	80	123	81	102
Potters	80	22	74	10
Plumbers, painters	87	20	73	23
File-makers	78	10	57	56
Copper manufacturers . .	71	6	45	3
Gunsmiths	78	4	74	—
Printers	68	2	65	2
Glass-makers	81	2	71	8
Chemical manufacturers . .	71	—	85	3
Occupied and retired males	78	1	68	1
Clergy	45	—	48	—
Coal-miners	61	—	53	—
Shipbuilding	64	—	55	—
Slaters, tilers	117	—	71	—
Furriers, skinners	82	—	115	—

Here are stated for two decennial periods all occupational groups with comparative mortality figures from lead poisoning above the standard set by occupied and retired males. Out of nine groups, in 1900–02 only two were markedly low for cancer, while two were markedly high; in 1910–12 only one group, printers, is rather low, and only one, plumbers, is high. A few other groups with no cases of lead poisoning are also given in order to show that lower and higher cancer figures, with more pronounced variations in rise or fall, are to be found in other occupations than the "lead" occupations.

These data do not reveal the suggested connexion between cancer and lead poisoning.

I am, Sir, yours faithfully,

EDGAR L. COLLIS.

Welsh National School of Medicine, Cardiff,
June 10th, 1924.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WHITSUNTIDE ADJOURNMENT.

ON June 6th the House of Commons adjourned for the Whitsuntide recess until Monday, June 16th.

THE HOUSING PROPOSALS.

On June 3rd the House went into Committee on the money resolution on which to found the Housing (Financial Provisions) Bill, Mr. R. YOUNG, Chairman of Committees, in the chair.

Mr. CLYNES, Lord Privy Seal, formally moved the following resolution :—

> That it is expedient—
>
> (*a*) To authorise the payment, out of moneys provided by Parliament, of contributions towards the expenses incurred in connexion with the provision of houses of the type and size mentioned in Subsection (2) of Section 1 of the Housing, &c., Act, 1923, which are completed before the first day of October, 1939, not exceeding in the case of any house which is subject to special conditions, whether as regards rent or lettings or disposal or otherwise, a sum of £9, or (if the house is situated in an agricultural parish in England or Wales, or in a rural area in Scotland) a sum of £12 10*s.* payable annually for a period not exceeding 40 years, and in the case of any house which is not subject to such special conditions a sum of £6, payable annually for a period not exceeding 20 years; and
>
> (*b*) To make provision as to such special conditions and, in the case of houses which are subject to special conditions, to provide for the reduction or variation of the contributions in the event of any of the special conditions not being complied with; and
>
> (*c*) To make provision for the withholding of contributions or the reduction or variation of contributions except in the case of houses completed before certain dates; and
>
> (*d*) To make provision for the amendment of the financial provisions of the Housing, &c., Act, 1923, and for other purposes incidental thereto or connected therewith.

Mr. WHEATLEY, Minister of Health, in explaining the Government's housing proposals, claimed that the Act of 1923 had been a complete failure. Something like 100,000 new houses per annum would be required to prevent the housing shortage increasing. On May 1st of this year 4645 houses had been completed and 12,738 were under construction, making a total of 17,383 either completed or under construction by local authorities for the purpose of letting. Assuming that all the houses were completed by Oct. 1st, the fact would remain that the housing conditions of the people who lived under the worst conditions in this country were considerably worse than when the present Act was introduced about 12 months ago. Not a single one, so far as he could ascertain, of the 32,000 houses being erected by what was called private enterprise was for the purpose of letting to the people who were so much in need of houses. His scheme, so far as the building industry was concerned, would work automatically. At the end of three years' building they would take stock, and if the average output of houses agreed upon between the State and the industry was not maintained then the agreement automatically terminated. On the other hand, if the output of houses was maintained the agreement automatically proceeded for a further period and they took stock again, and so on to the end of the 15-year period, when they would have produced 2,500,000 houses. The building industry had pointed out to him that they could not continue to give houses at present prices unless the prices of materials were maintained at their present level. That seemed perfectly reasonable. He had drafted a Bill by which he would ask Parliament to give him drastic powers for dealing with profiteering in building materials. The brick manufacturers had intimated that they were prepared to take the price of January, 1924, as the basis of the price for future building under his scheme. They were also prepared to see it enacted in an Act of Parliament that it should be an offence or the basis of investigation of an offence that a price was charged by any manufacturer higher than that charged in January, 1924, unless they could prove that the increase was justified by reason of increased wages or similar cause. He did not think that the nation could get a more generous offer. It was further proposed to set up three committees. One would be composed of builders and operatives, another of manufacturers of materials and merchants, and the third was a prices survey committee. These three committees would be interlocked by three representatives of each sitting on a super-committee, a national building committee to be set up by the Ministry of Health. There would be no representatives of the local authorities or the State on these committees because they would act simply in an advisory capacity. The subsidy for which he asked the sanction of Parliament was £9 a house per annum for 40 years and in defined agricultural areas of £12 10*s.* per house per annum. The amount of the subsidy was to be revised every three years, not for the houses that had been built, but in the light of existing circumstances for the houses of the future. In one respect he was sorry that he had to yield to the local authorities. They insisted that he would not interfere with the size of houses laid down in the 1923 Act. He would have liked to add 100 ft. to the maximum. He found that within their discretion, which was from 550 ft. to 950 ft., the average size of houses being built by local authorities in England and Wales was 817 ft.

The House went into Committee on June 4th and resumed the discussion of the money resolution on which to found the Housing (Financial Provisions) Bill.

During the course of the discussion Mr. WHEATLEY accepted an important amendment, moved by Sir G. MCCRAE, the Liberal Member for Stirling and Falkirk, to paragraph (*c*) of the resolution providing, in the absence of adequate arrangements, for the necessary increase in the supply of labour and materials at reasonable prices, for the withholding of the subsidy, or the reduction or variation of the subsidy except in the case of houses complete before a certain date.

The resolution as amended was agreed to.

Housing Bill Introduced.

On June 5th the House considered the money resolution in connexion with the Government's Housing Bill, which was agreed to in Committee with an amendment on the previous day.

Mr. WHEATLEY moved an amendment which he said arose out of the amendment agreed to on the previous night. If they were to proceed with the resolution as it stood, it would exclude certain contingencies under which they would want to suspend the operations of the Act. He had submitted the words he proposed to move both to the mover of the amendment (Sir G. McCrae) and to Mr. Neville Chamberlain. His amendment was to insert in paragraph (*c*), after the words "to make provision in," the following words: "Certain contingencies including contingencies which may arise in." The effect, he said, was not to confine the powers of the Government to the shortage of labour and materials, but to leave them in the wider sense while including the amendment carried on the previous night.

The amendment was agreed to and the resolution as amended was agreed to.

Mr. Wheatley then, amid cheers, brought in the Housing (Financial Provisions) Bill, which was read a first time.

Wednesday, June 4th.

Cost of Health Insurance Central Administration.

Mr. Trevelyan Thomson asked the Minister of Health what was the cost of the central administration of National Health Insurance benefits for insured persons—i.e., by the Ministry of Health, the Welsh Board of Health, and the Scottish Board of Health respectively.—Mr. Wheatley replied. The approximate total cost of the central administration of National Health Insurance (including expenses incurred by other Government departments and certain amounts recoverable from insurance funds) in the year 1923 was as follows :—England : Ministry of Health, £871,000 ; Wales : Welsh Board of Health, £70,000 ; Scotland : Scottish Board of Health, £123,000.

Subsidised Midwives for Rural Areas.

Mr. Black asked the Minister of Health whether, in the interest of the preservation of the lives of mothers and new-born babies, he would make it a statutory obligation upon county councils to provide a sufficient service of subsidised midwives to cover the necessities of the whole of the rural areas of Great Britain.—Mr. Wheatley replied : I could not undertake to introduce legislation for this purpose at the present time. The large majority of county councils are already exercising their present powers by aiding the provision of midwives in rural areas, and I am willing to consider any proposals for additional assistance in this direction. I propose shortly to issue a circular calling attention to the necessity for an efficient midwifery service in every area.

Sanatoriums for Advanced Consumption Cases.

Mr. Black asked the Minister of Health how many sanatoriums for the reception of incurable and dying cases of tuberculosis there were in Great Britain and what proportion of such cases died away from public institutions of this character.—Mr. Wheatley replied : Of the institutions which I have approved for the treatment of tuberculosis in England and Wales, 99 are available wholly or mainly for the reception of advanced cases of the disease. The majority of the remaining institutions, other than children's institutions, also admit a proportion of advanced cases. As regards Scotland, a question should be addressed to the Senior Secretary for Health for Scotland. I cannot say what proportion of deaths from tuberculosis occur elsewhere than in approved sanatoriums, but in 1922 approximately two-thirds of the total deaths from tuberculosis in England and Wales occurred elsewhere than in institutions.

Ex-Service Men and Tuberculosis.

Mr. Pielou asked the Minister of Health the number of ex-Service men who had died during the last nine years from tuberculosis as a result of their war service.—Mr. F. O. Roberts replied : The number of ex-Service men who have received an award from the Ministry of Pensions in respect of tuberculosis and who have died from that disease is, I regret to say, 15,770.

Thursday, June 5th.

Births and Deaths Registration Bill.

Lieut.-Colonel Fremantle introduced the Births and Deaths Registration Bill, a measure to amend the law relating to certification of still-births and deaths and the disposal of the dead. The Bill, which is supported by a doctor and a lawyer from each political party, was read a first time.

Examination of Young Persons for Factory Work.

Mr. Graham White asked the Home Secretary if it was his intention to raise the age of examination of young persons for factory employment from 16 to 18 in order to link up the inspections under the Factory Act with that of the school medical services and other public health services.—Mr. Henderson replied : I have decided, after consultation with the Ministry of Health, to include in the Factories Bill the recommendation in favour of raising the age which has been made by the Departmental Committee presided over by my hon. friend the Parliamentary Under-Secretary of State for the Home Office. The hon. Member will find the provision in Clause 91 of the Bill.

Danger to Health of Pneumatic Tools.

Mr. Benjamin Smith asked the Home Secretary whether his attention had been called to the injury to health suffered by men using pneumatic tools ; and whether he would cause an inquiry to be held into the matter.—Mr. Henderson replied : I received recently a communication on this subject from the Transport and General Workers' Union, but no definite evidence of injury has so far been furnished. I will have the matter looked into, but I shall be glad if the hon. Member can supply me with particulars of actual instances of workmen who have suffered injury to health from this cause with a view to facilitate inquiry.

Children and Poor-law Relief.

Mr. Graham White asked the Minister of Health if he would give, as on the last convenient date, the number of children who were in receipt of Poor-law relief owing to the unemployment of their parents.—Mr. Greenwood replied : The number of children under 16 years of age in England and Wales dependent upon parents who were in receipt of Poor-law relief on account of unemployment was about 250,000 in March of this year.

Nursing Service in Mental Hospitals.

Mr. Hore-Belisha asked the Minister of Health whether the Departmental Committee on the Nursing Service in Mental Hospitals had yet reported ; and, if so, whether the report would be published.—Mr. Greenwood replied : The report is nearing completion and will be published as early as possible.

Mr. Buckle asked the Minister of Health whether, in the case of the additional London County Council asylum about to be opened in the neighbourhood of Epsom under the name of West Park Mental Hospital, he would say whether it was intended for the care and treatment of certified patients ; what accommodation it would afford ; and whether voluntary boarders were to be admitted.—Mr. Greenwood replied : The answer to the first part of the question is in the affirmative. The institution will provide accommodation for 1732 patients. My right hon. friend regrets that the law does not allow voluntary boarders to be admitted for treatment in public mental hospitals.

Physical Condition of Army Recruits.

Mr. Thurtle asked the Secretary of State for War whether he was aware that, in the year 1921–22, out of 106,954 persons offering to enlist, 59,736, or 56 per cent., were rejected for physical reasons, whilst in the year 1912–13 only 2·7 per cent. were so rejected ; and whether he could give any reasons for the difference.—Mr. S. Walsh replied : The percentages of rejection are 56 per cent. and 27 per cent., not 2·7 per cent. The higher percentage of rejection in the later year is no doubt the effect of war conditions upon the physique of the population, but I am glad to say that the quality of the recruits now coming forward is steadily improving.

Friday, June 6th.

Departmental Committee on Health Insurance.

Sir John Marriott asked the Minister of Health whether the Inter-Departmental Committee on Health and Unemployment Insurance (1922) was still in being ; whether that Committee had presented any reports since that dated March 17th, 1922 ; whether any further or final report from the Committee might be expected, and, if so, when.—Mr. Greenwood (Parliamentary Secretary Ministry of Health) replied : The answer to the first part of the question is Yes. The Committee presented a third interim report on Feb. 23rd, 1923. No further report has been prepared and it is doubtful whether the Committee can profitably resume its deliberations having regard to the fact that a Royal Commission is about to be appointed to investigate the working of the system of health insurance, and that modifications of the Unemployment Insurance Scheme are also under consideration.

Medical News.

University of Cambridge.—It was announced by the Vice-Chancellor on June 10th that Sir Jeremiah Colman had given £2000 to establish a library for the School of Biochemistry.

University of Oxford.—The following candidates passed in the recent examination :—

Diploma in Public Health.—Part I. : Capt. T. O. Thompson, D.M., St. John's College. Part II. : J. G. Johnstone, B.M., and Capt. T. O. Thompson, D.M., St. John's College.

In Convocation on June 3rd the reappointment was approved of Dr. E. W. Ainley Walker, Fellow of University College, as Dean of the Medical School. In congregation, on the motion of Regius Professor of Medicine, Sir Archibald Garrod, a proposal was accepted to lend £4000 from the Special Reserve Fund to extend the Department of Human Anatomy in order to house the Rolleston collection of crania and skeletons and to provide suitable laboratories for the instruction of students in physical anthropology.

University of London.—In the Final Examination for the degree of M.B., B.S., held last month, the honours list is as follows :—

Kathleen D. Arnsby (*b*), London (R.F.H.) School of Medicine for Women ; E. Gallop (*a*, *e*), St. Bartholomew's Hospital ;

Dorothy Gibson (*a*, *d*, University Medal), London Hospital; W. O. C. Jarratt (*d*), St. Thomas's Hospital; J. Maxwell (*a*, *e*), St. Bartholomew's Hospital; A. T. Rogers (*d*), Guy's Hospital; W. P. H. Sheldon (*a*), King's College Hospital; Hilda N. Stoessiger (*b*), London (R.F.H.) School of Medicine for Women; T. C. Summers (*d*), London Hospital; H. F. Walker (*e*), Middlesex Hospital.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The Croonian lectures will be given by Sir Leonard Rogers on June 17th, 19th, 24th, and 26th, the subject being Researches on Leprosy and their Bearing on the Treatment of Tuberculosis. The Bradshaw lecture will be given by Dr. F. John Poynton on Nov. 4th on the Prevention of Acute Rheumatism. The Mitchell lecture will be given by Sir StClair Thomson on Nov. 6th on Tuberculosis of the Larynx, and its Significance to the Physician. The FitzPatrick lectures will be given by Dr. Charles Singer on Nov. 11th and 13th on the History of Anatomy. The above lectures will be delivered at the College, Pall Mall East, at 5 P.M. The Lloyd-Roberts lecture will be delivered at the Medical Society of London, 11, Chandos-street, W., by Dr. Herbert R. Spencer, on Nov. 19th, on the Renaissance of Midwifery.

CONFERENCE ON INFANT WELFARE.—The Third English-speaking Conference on Infant Welfare will be held at Caxton Hall, Westminster, on July 1st to 4th, under the auspices of the National Association for the Prevention of Infant Mortality and the National Baby Week Council.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—It has been arranged to hold in July a two weeks' course in ophthalmology (July 7th to July 18th) at the Royal Eye Hospital, Southwark. The ground covered will include clinical cases, followed by a lecture on subjects of particular interest to those engaged in the study of ophthalmology. Also a fortnight's intensive course (July 21st to August 2nd), including all the special and general departments of medicine and surgery at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham). There will be the following courses in August: Diseases of children at the Queen's Hospital for Children; diseases of the chest at the Brompton Hospital (both courses date from August 11th to August 23rd) and neurology at the West End Hospital for Nervous Diseases (August 18th to Sept. 6th). Copies of the syllabus of the above courses with full particulars can be obtained from the Secretary, Fellowship of Medicine, 1, Wimpole-street, W.1.

LONDON HOSPITAL.—On June 4th a framed testimonial, a gift of the Carnegie Hero Fund, was presented by Lord Knutsford to Mr. Ernest Harnack in recognition of his work in connexion with the X ray department. Mr. Harnack entered the radiographic department in 1897, and in carrying out his pioneer work he lost both his arms. In these early days the opacity of lead glass to X rays was not known. Mr. Harnack also received a grant of £75 a year from the Carnegie Hero Fund, in addition to the £285 a year given by the hospital. At the same meeting Lord Knutsford announced that a special department for sun-bath treatment for general tuberculosis was to be erected; he also stated that Sir H. M. Mallaby-Deeley, in place of his original offer of £10,000, had offered a further £15,000 under certain conditions for the massage department. It was also stated that a special research department was being organised under Dr. George Riddoch, assisted by Dr. Henry Head.

THE MINISTER OF PENSIONS IN IRELAND.—Our Irish correspondent writes:—Mr. F. O. Roberts, British Minister for Pensions, accompanied by Mr. J. W. Muir, Parliamentary Secretary, has been paying a visit to Ireland, south and north, during the Whitsuntide recess. In his speech to a gathering of ex-Service men Mr. Roberts stated that there was something wrong with the work of the Ministry when, in so high a proportion as 60 per cent., appeals to the Pensions Appeals Tribunal were successful. Mr. Muir, in reply to criticisms concerning medical boards, said that the Ministry wished it to be understood that they did not want medical men to make their assessments from any point of view of economy, or any other point of view than the merits of the cases. They wanted every medical board to act independently of any other medical board in the country, and not to consider how its average of assessments would compare with the average of any other board. In cases where there was any doubt, they wanted the benefit of the doubt to be given to the men, and they wanted that to be understood by all their officers. If, however, the Ministry does not wish for any approximation to the average in the work of individual boards and areas, it is not easy to see why the central office is so assiduous in drawing the attention of local administrators to variations from the average. Mr. Roberts visited the Ministry's Orthopædic Centre at Blackrock, and paid a high compliment to the surgical work performed there.

Dr. R. A. Lyster, county medical officer of health for Hampshire, has been elected President of the Society of Medical Officers of Health for the session 1924-25.

EUGENICS EDUCATION SOCIETY.—To-day (Friday), at 3 P.M., Dr. W. A. Potts, of Birmingham, will open a conference on the Desirability of Greatly Increased Institutional Accommodation for Mental Defectives, to be held at the rooms of the Royal Society, Burlington House, Piccadilly, London; Major Leonard Darwin, Sc.D., will be in the chair. Members of the society and all interested are invited to attend.

ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM.—The following members of the medical profession have received promotion in the Order: Serjeant-Surgeon Sir Richard Havelock Charles to be Knight of Justice; Lieut.-Colonel G. H. L. Hammerton, R.A.M.C. (T.F.), Sir Robert W. Philip, Lieut.-Colonel G. Horne, and Colonel Sir Thomas Oliver to be Knights of Grace; Dr. S. M. Hebblethwaite, Surgeon Lieut.-Colonel J. H. Hacking, Surg.-Commander G. O. M. Dickenson, R.N., Dr. A. S. Allan, Dr. A. D. Cameron, Lieut.-Colonel H. Ross, I.M.S., and Colonel Sir Edward N. Thornton are appointed Esquires.

UNIVERSITY OF DURHAM MEDICAL GRADUATES ASSOCIATION.—The annual general meeting will be held on Thursday, June 26th, at 4.30 P.M., at the rooms of the Medical Society, 11, Chandos-street, Cavendish-square, London, W. Following the ordinary business of the meeting Dr. G. de B. Turtle will read a short paper entitled An Attempt to Classify Certain Types of Pyrexia. A small informal dinner will be held the same evening at the Criterion Restaurant, Piccadilly-circus, at 7.45 (price of the tickets 10*s.* 6*d.*, exclusive of wines, which sum will be collected at the table). Any member wishing to attend will greatly facilitate the work of Dr. F. W. M. Pratt, the secretary, 15, Clarges-street, Mayfair, W. 1, by replying before June 16th.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The election of President, Vice-President, and Council and Secretary of the Royal College of Surgeons in Ireland was held on June 2nd. The following were elected:—President: Mr. Richard C. B. Maunsell. Vice-President: Mr. Andrew Fullerton. Secretary of College: Sir Frederick C. Dwyer. Council: John B. Story, Sir Thomas Myles, Major-General R. H. S. Sawyer, Arthur W. W. Baker, Sir Arthur Chance, Sir Robert H. Woods, Richard Lane Joynt, Thomas Eagleson Gordon, Sir Frederick C. Dwyer, Alexander J. Blayney, Sir William Taylor, Trevor Nathaniel Smith, Seton Pringle, Sir William I. de Courcy Wheeler, Sir C. Arthur K. Ball, Richard Atkinson Stoney, Edward Sheridan, William Pearson, Adams A. McConnell. Mr. Maunsell is a graduate in medicine and surgery of the University of Dublin, and for several years held the position of University examiner in surgery. He has been a Fellow of the Royal College of Surgeons since 1900, and was elected to the council in 1904. Two years ago he was unanimously elected to the position of vice-president. Mr. Maunsell is the senior surgeon to Mercer's Hospital, having been appointed to the staff of that hospital in 1898, and lectures and writes on surgical subjects. During the war Mr. Maunsell for a time served in France as surgical specialist to the Dublin 83rd General Hospital.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, June 17th.

SPECIAL GENERAL MEETING OF FELLOWS: at 5 P.M.
To be followed immediately by a
GENERAL MEETING OF FELLOWS:
Ballot for election to the Fellowship.

Thursday, June 19th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases:
Dr. G. Pernet: (1) Porokeratosis; (2) Extensive Dermatitis Factitia.
Other cases will be shown.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, W.

THURSDAY, June 19th.—8.15 P.M., Annual General Meeting, preceded by a Demonstration at 7.45 of Leishmania and Other Allied Flagellates.

The paper, illustrated by lantern slides, will be read by Lieut.-Colonel T. McCombie Young, I.M.S., on Fourteen Years' Experience with Kala-Azar Work in Assam.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W. 1.

Monday, June 16th, to Saturday, June 21st.—Chelsea Hospital. Daily Operations, &c. Mon., 2 P.M., Mr. L. C. Rivett: Lecture Dem., Procidentia. Tues., 2 P.M., Mr. Victor Bonney: Dysmenorrhœa. Wed., 2 P.M., Mr. Stanley Dodd: Extra-Uterine Gestation. Sat., 11 A.M., Mr. Aubrey Goodwin: Path. Dem.—Children's Clinic. Mon., 2 P.M., Dem. of Cases. 2.30 P.M., Mr. Winsbury White: Stone in Children. 4 P.M., Prof. Lovatt Evans: Acidosis. At College Farm, Finchley, Tues., 2.30 P.M., The Production of Certified Milk on a Model Farm. 3.30 P.M., Dr. Bernard Myers: The Feeding of Infants and Older Children. At Children's Clinic, Thurs., 10 A.M., Dem. of Cases. 11.30 A.M., Dr. T. Joekes: The Blood Diseases of Children.—London School of Tropical Medicine. Tuesdays and Thursdays at 2 P.M., Demonstrations on Diseases of Tropical Countries.—Royal Northern Hospital, in conjunction with the Royal Chest Hospital, City-road. Special Course in Intensive Medicine and Surgery (first week).—St. Peter's Hospital for Stone. Clinical work and special Lectures daily (first week).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, June 16th.—12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.

Tuesday.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair; Surgical Out-patients.

Wednesday.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Pernet: Skin Dept.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Dr. Scott Pinchin: Diseases of Heart. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 A.M., Mr. Dudley Buxton: Dental Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

Post-Graduate Course.

Monday, June 16th.—12 noon, Dr. Riddoch. Lecture: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Birley. Lecture: Subacute Combined Degeneration of the Cord.

Tuesday, June 17th.—12 noon, Dr. Greenfield. Lecture: Cellular Reaction in Nervous System. 2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Risien Russell. Lecture: Myasthenia Gravis.

Thursday, June 19th.—12 noon, Dr. Riddoch. Lecture: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Syphilis of Nervous System.

Friday, June 20th.—2 P.M., Dr. Gordon Holmes: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Physical Exercises.

Applications should be addressed to the Secretary, Medical School, National Hospital for the Paralysed and Epileptic, Queen-square, London, W.C. 1.

J. G. Greenfield, Dean.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

Tuesday, June 17th.—5 P.M., Dr. Knowsley Sibley: Electro-Therapeutics.

Thursday.—5 P.M., Dr. Griffith: Primary Lesion of Syphilis.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

Thursday, June 19th.—5 P.M., Mr. Richard Lake: Middle-Ear Disease. (Geoffrey E. Duveen Lectures in Otology).

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES (3.30 P.M.)

Monday, June 16th.—(At the Shaw-street Hospital.) Mr. Leyland Robinson: The Fibroid Uterus.

Tuesday.—(At the Maternity Hospital.) Miss Nicholson: Syphilis, Antenatal and Postnatal.

Wednesday.—(At the St. Paul's Eye Hospital.) Mr. H. Haward Bywater: Some Clinical Cases.

Thursday.—(At the St. George's Hospital.) Dr. F. H. Barendt: Skin Cases.

Friday.—(At the Eye and Ear Infirmary.)

Appointments.

Cumming, J. K., M.B., Ch.B. Aberd., has been appointed Medical Officer of Health, Great Harwood.

Giffen, T. M., F.R.C.S. Edin., L.R.C.P. Edin., to be one of the Medical Referees under the Workmen's Compensation Act for the Districts of Birkenhead and Runcorn County Courts.

Gillies, P. H., M.B., C.M. Edin., County Medical Officer for Argyll.

Westminster Hospital: Price, Thomas C., F.R.C.S. Eng., Surgical Registrar; Lloyd, W. E., M.B. Lond., M.R.C.P. Lond., Medical Registrar.

Vacancies.

For further information refer to the advertisement columns.

Alton, Hampshire, Lord Mayor Treloar Cripples' Hospital and College.—Jun. Asst. R.M.O. £250.

Bahamas.—Bacteriologist and Asst. M.O.H. £600.

Barbados General Hospital.—Res. S. £330.

Barnsley, Beckett Hospital and Dispensary.—Sen. H.S. £220.

Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. £150.

Cardiff, Welsh National School of Medicine.—Lecturer in Special Sense Physiology. £750.

Dreadnought Hosp., Greenwich, S.E.—H.S. and H.P. Each £150.

Dundee, King's Cross Infectious Diseases Hospital.—Sen. R.M.O. £350.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. £125.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hong-Kong Government.—Two M.O.'s. Also Asst. Port Health O. Each £600.

Leeds City.—Chief Clin. Tuberculosis O. £900.

Leeds University, Dept. of Pathology and Bacteriology.—Lecturer in Chemical Pathology. £600.

Liverpool, Royal Southern Hospital.—Hon. Asst. P. and Hon. Asst. S.

Liverpool, Samaritan Hospital for Women, Upper Parliament-street.—Hon. Asst. S.

Llanelly Borough Education Committee.—Dental S. £500.

London Hospital Medical College.—University Chair of Medicine. £2000.

Manchester, Hulme Dispensary, Dale-street.—Res. M.O.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—Sen. and Jun. H.S.'s. £130 and £100 respectively.

Manchester, St. Mary's Hospitals.—Three H.S.'s Each £50.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. Path. £250. Also R.M.O. £200.

Paddington Board of Guardians.—Res. Asst. M.O. £327 12s.

Putney Hospital, Lower Common, Putney, S.W.—Res. M.O. £150.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Sen. Res. M.O., Two Asst. Res. M.O's. £100 and £80 respectively.

Queen Mary's Hospital for the East End, Stratford, E.—H.P., 2 H.S.'s, Obstet. H.S., also H P. and Cas. O.

Rochdale Infirmary.—M.O. in charge of X Ray, &c., Dept.

Royal Chest Hospital, City-road, E.C.—P. in charge of Out-patients.

Royal Ear Hospital, Dean-street, Soho.—Registrar. £50.

Royal London Ophthalmic Hospital, City-road, E.C.—H.S. £150. Also 2 Refraction Assts. Each £100.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Non-Res. Cas. O. £150. Also Hon. P. to Out-patients.

St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.—Pathologist. £100.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Sheffield Royal Infirmary.—Ophth. H.S., H.S., Asst. Cas. O., and H.S. to Ear, Nose, and Throat Dept. Each £60.

Stockport Infirmary.—Sen. and Jun. H.S.'s £250 and £175 respectively.

University College Hospital, Gower-street, W.C.—Hon. Anæsth.

University of London.—External Examiners.

West Bromwich and District Hospital.—Res. H.S. £220.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., Res. Cas. O. Each £100.

Births, Marriages, and Deaths.

BIRTHS.

Anderson.—On June 4th, at Albyn-terrace, Aberdeen, the wife of William Anderson, F.R.C.S., of a daughter.

Beadon.—To Richard à Court Beadon, and Dr. Mary O'Brien Beadon, M.B., B.S., W.M.S.I., Superintendent, Govt. Victoria Hospital for Women, Madras, on 28th April, 1924—a son.

Hampton.—On June 3rd, the wife of F. Anthony Hampton, M.B., of Blue Spur, Chesham Bois, of a daughter.

Shattock.—On June 10th, at Mecklenburgh-square, to F. Mackenzie, M.B., B.S., wife of C. E. Shattock, M.S., F.R.C.S., of Harley-street, of a son.

MARRIAGES.

Aymer—Floyd.—On June 5th, at St. Andrews, Boscombe, Charles Alastair Aymer, M.B., to Winifred Eileen Floyd, adopted daughter of W. Child Clark, Esq., of Michelgrove House, Boscombe.

Dorgan—Stapleton-Bretherton.—On June 5th, at St. Mary's, Cadogan-street, Lieut.-Colonel James Dorgan, R.A.M.C., to Monica, daughter of the late Mr. and the late Hon. Mrs. Stapleton-Bretherton, of Rainhill, Lancashire.

Hayes—Herron.—On June 4th, in London, Reginald Hewlett Hayes, M.R.C.S., to Alice, widow of Kenneth Chester Herron.

Morgan—Relton.—On June 5th, at St. Matthew's Church, West Kensington, Robert William Morgan, M.D., to Grace, daughter of the late F. H. Relton.

DEATHS.

Allen.—On June 4th, at "Marchings," Folkestone, very suddenly, Colonel Sydney Glenn Allen, A.M.S. (retired).

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE FRAMINGHAM HEALTH AND TUBERCULOSIS DEMONSTRATION.[1]

COMMUNITY PREVENTION, CONTROL, AND TREATMENT OF DISEASES, AS CARRIED OUT AT FRAMINGHAM, MASSACHUSETTS, U.S.A.

By Ralph C. Matson, M.D.,
DIRECTOR OF THE NATIONAL TUBERCULOSIS ASSOCIATION, U.S.A.

One of the first essentials of community prevention, control, and treatment of disease is that of education. The official health agency, receiving its money by budget, is usually restricted in its expenditure, and either unable or unwilling to expend money in experiments or demonstrations. It is therefore the duty of non-official or volunteer health organisations to demonstrate the value of our present knowledge regarding disease prevention, control, and treatment. Practically all units of community schemes for disease prevention, control, and treatment now utilised in America, such as sanatoria, open-air schools, preventoria, the public health nurse, &c., were shown to be of value by non-official organisations, before public officials were willing to accept them and expend funds for their maintenance.

The Community Health and Tuberculosis Demonstration at Framingham, Massachusetts, is an example of what can be accomplished by demonstration by a non-official organisation. It was established on Jan. 1st, 1917, by the National Tuberculosis Association with the financial assistance of the Metropolitan Life Insurance Company, to show that by the expenditure of a sufficient amount of funds it was possible to diminish both morbidity and mortality from tuberculosis in a community with an average equipment for health work.

The Metropolitan Life Insurance Company is interested in tuberculosis because 16 per cent. of the deaths in the industrial department are due to this disease. In 1915 the Company paid $4,000,000 on account of 14,325 policy-holders dying from tuberculosis. Tuberculosis is responsible for approximately one in every ten deaths in America, and one in every three industrial deaths is due to this disease. The National Tuberculosis Association alone, and through its associated State and local organisations, is expending upwards of $5,000,000 annually in its efforts to prevent, control, and eliminate tuberculosis, and it is quite natural to ask, "Of what value are present-day methods of disease prevention and control, and is this enormous expenditure of effort and money worth while?" The story of Framingham answers the question.

The Scope of the Work Attempted.

Framingham was selected for the demonstration because it represented a typical American community of about 17,000 people, with an average death-rate, average population, and average conditions, socially and industrially. Moreover, the local officials, voluntary health and civic organisations, expressed a desire for the demonstration, and assured coöperation. The object of the demonstration was essentially to discover all cases of tuberculosis in the community, to determine the economic and social factors in disease causation with special reference to tuberculosis, to apply the best-known methods of treatment, to develop a comprehensive programme of prevention, and organise the community for disease prevention and health creation.

One of the first things undertaken at Framingham was to secure the coöperation of local physicians and townspeople; the former was accomplished by organising a medical club, before which important lectures and clinics were given, concerning various phases of the tuberculosis problem and related medical problems. This also developed certain standards for tuberculosis diagnosis, and elevated the methods of diagnosis and treatment of this disease. Besides it secured the support and coöperation of local physicians almost to a man. The coöperation of the people of Framingham was secured by acquainting them with the motives, methods, and practical objects of the demonstration by means of special literature, daily press articles, numerous meetings, and the appointment of local representatives on the National Committee and the organisation of many local committees, representing various community interests, such as a local executive committee, a local advisory committee, an exclusion committee (whose duty it was to detect an invasion of the community by migratory consumptives), an industrial health committee, an infant welfare committee, neighbourhood committees, &c.

The work began quite naturally with a series of investigations with reference to the incidence of tuberculosis infection and presence of the disease, the hygienic hazards, community resources, &c. Among the more important investigative activities may be mentioned:—

1. A general sanitary survey, including a survey of industrial hazards, school and factory conditions, including problems of general sanitation, cleanliness facilities, illumination, ventilation, heating, dust, fumes, safety devices, milk and food control, morbidity and mortality statistics.

2. Not only was the community's statistical background studied, but the people themselves were studied, by a sickness survey, designed to give a cross-section picture of the amount of disease of all kinds in the community and serve as a measure for comparing illness findings at the beginning, with similar findings at the end of the demonstration. This census was similar to the sickness canvasses and health censuses frequently conducted by life insurance companies, and was carried out by the trained agents of several large insurance companies, loaned for the purpose, assisted by trained nurses. This survey disclosed 1·8 per cent. incapacitating illnesses, 6·2 per cent. for all forms of illness, and only 0·24 per cent. tuberculosis (a point which shall be discussed later); 81·1 per cent. of the individuals recorded ill were receiving medical attention.

3. A number of medical examination campaigns were held. Not only industrial workers, but 14,000 of the 17,000 people living in Framingham, were given a thorough medical examination; this revealed an active tuberculosis present, in 1 per cent. of the population, with a prevalence of illness and disability of all kinds of 77 per cent.

4. A study of infant and child life in Framingham was made by visiting every home where a birth had taken place during the previous year, and recording certain essential prenatal, obstetric, and postnatal facts. A tuberculin survey was made by an expert on 460 children, ranging from 1 to 7 years of age. This was done to throw light, if possible, on the sources of childhood infection, and to select those most needing special care. It was also done to determine the reaction percentages of different nationalities, neighbourhoods, &c., as well as to determine the reliability of the tuberculin test in young age-groups as an index of tuberculous disease. This study revealed 33 per cent. positive reactions, which differed significantly in different race stocks. Of special interest are the findings in Irish and Italian race stocks. While the Italian stock gave the highest of positive reaction, very few cases of active tuberculosis were found among them either in adults or children. On the other hand, while the percentage of positive reactions among the Irish stock was low in Framingham, as elsewhere, the Irish stock contributes more than its share to the morbidity and mortality-rates. Re-examination of these children at subsequent dates disclosed no cases of demonstrable tuberculosis.

5. A careful investigation was made of the influenza sequelæ, which revealed many interesting things, among which was the relative degree of protection in the tuberculosis group, of which only 4 per cent. became afflicted with influenza, while 12 per cent. of the population at large was estimated to have had the disease. It is also interesting to note, in connexion with the incidence of influenza in race stocks, that while the tuberculosis incidence among the Irish was eight times that of the Italians, the Italians had an influenza incidence four times greater than the Irish.

6. A census was made of all individuals in Framingham, covering such environmental factors as hygiene, housing, economic status, &c.

7. A survey was made of tuberculosis infection among cattle supplying milk to Framingham.

"*Community Diagnosis*" *and* "*Community Treatment.*"

As a result of the foregoing activities a "community diagnosis" was made. This was followed by a "community treatment," the basic principle of which was to continuously encourage the community to meet its own health requirements and place the non-experimental phases of the demonstration on a permanent basis. The "community treatment" comprised a number of activities, the most valuable of which was an expert consultation service, offering consultations to local physicians, factory medical and nursing staffs on cases of suspected tuberculosis or respiratory infections. This resulted in earlier diagnosis of tuberculosis, tripled reporting of tuberculosis, and tremendously increased the number of tuberculosis cases disclosed. It also encouraged the search for early tuberculosis and examination of contacts. This latter procedure resulted in the establishment of summer camps for pre-tuberculous children, as well as the establishment of domestic economy and good hygiene education for families having tuberculosis or under-par children.

The community was thoroughly organised, not only for the control of tuberculosis, but for general health and disease prevention. This included general community sanitation, the promotion of infant welfare work, school health work, industrial health work, tuberculosis nursing, and a programme of education, which included lectures to mothers, and to industrial groups and health cinema programmes. These activities popularised health knowledge in the community and improved municipal methods of disease prevention, especially tuberculosis. The tuberculosis clinic was reorganised. Tuberculosis cases were placed under supervision as rapidly as they were discovered. Those requiring institutional care were sent to suitable sanatoria or hospitals, others were cared for in the dispensary or at home. The local board of health, the school committee, the Park Commission, the Framingham Hospital, the Civic League, and Red Cross were either developed or expanded, and aided directly or indirectly along financial and other lines.

---

[1] A paper read at the First International Congress of the People's League of Health at Wembley on May 23rd, 1924.

The Changes which have Taken Place.

The foregoing is thus a brief sketch of the demonstration's purpose, its organisation, and activities. The changes which have taken place in Framingham may be summarised as follows. The demonstration is now in its last year, but has been so successful and convincing that the community has taken over all prenatal infant and pre-school work, all the school health work, and general health administration of the community, including tuberculosis nursing, tuberculosis and venereal disease clinic work, and to a large extent the health production and disease preventive activities in the industrial age-group; and, what is more significant, next year every activity undertaken in the demonstration and every suggestion made will be taken over as a community activity.

When the demonstration began, Framingham had only just appointed a full-time health officer, who had under his supervision the following activities: laboratory examinations, quarantine, care of tuberculosis cases, certain police duties, and a tuberculosis clinic. Within four years the board of health increased its budget 130 per cent. and established four infant clinics, one tuberculosis health station and clinic, with consultant on call at all times, one infantile paralysis clinic, one venereal clinic, a tuberculosis nurse visiting 100 patients, two infant and pre-school nurses visiting 450 babies, and three part-time infant welfare physicians.

Before the demonstration began there were 3039 children in Framingham schools with one part-time physician and one full-time nurse. Physical examinations were made only at request of the nurse. After five years of demonstration, at which time there was only a slight increase in the school population, the health organisation comprised one full-time physician, one nurse, one dental hygienist (who cleans mouths, holds tooth-brush drill, gives talks to classes, &c.), one dental clinic, and one director of physical education.

The Effect on Industrial Workers.

Naturally, the demonstration has evoked an intense interest in industry, as the highest death-rates are found in the industrial age-group. As a result of the demonstration, the devices for preventing accidents and procedures for improving the health of the workers have steadily increased. There are approximately 5000 industrial workers in Framingham, nearly half of whom are employed in one industry. When the health demonstration began the health work of this industry consisted of one nurse, one rest room, one-room clinic, a physician on call, and a sick benefit association. After five years of demonstration activity, the health equipment of this same industry consisted of one full-time physician, a three-room clinic, one full-time dentist, a dental clinic, two nurses, one rest room, complete surgical throat and ophthalmological outfits, and a sick benefit association assuring three weeks in the hospital in any one year if necessary. The plant was also organised on advanced democratic profit-sharing and management-sharing basis, with considerable participation in control by employees of different grades through industrial partnership, industrial associates, and shop committee devices. Compulsory examination of new employees is now carried out by the plant physician, this procedure being at the request of the works committee. It must be pointed out that medical and nursing facilities in industry can only functionate fully when developed and operated in very close coöperation with employer and employee, and should be used for the purpose of fitting the man to a job rather than as a means for rigidly weeding the unfit from industry. A Civic League was organised in 1917, and a year later opened its new building with a swimming pool and gymnasium open to the public. General health and educational work has been carried on regularly, and health clubs and community garden clubs are in operation. The two hospitals in Framingham have training schools and the student nurses assist in several important demonstration activities. One of these hospitals has a district nursing service.

The Park Commission has opened five playgrounds under the supervision of a physical director. General conditions in Framingham have undergone many constructive changes. The sewage system has been modernised, the milk-supply has been very much improved, the milk consumption has been doubled, and almost complete pasteurisation is in effect. Public spitting has been greatly reduced as a result of education and enforcement of city ordinances.

One of the most satisfying and significant results of the demonstration is the interest local physicians have taken in tuberculosis and their efforts to find new and early cases. This has been largely due to the highly efficient consultation service in charge of Dr. P. C. Bartlett, who with scientific skill and exceptional tact and judgment has made the service one of the most valuable features of the demonstration, and utilised by nearly all local physicians. The consultation service is not limited to tuberculosis work, but as far as possible it enters the field of general medicine. This service has attracted nation-wide attention, and is now in operation in Massachusetts, Illinois, New York, Oklahoma, Vermont, and Wisconsin.

The Results of the Investigations.

While the demonstration has been on a relatively small scale, it has revealed certain conditions, which one may say are representative of the average American community, and has brought out certain standards of community health work which can be advantageously applied to the country at large. Among the most important results of the investigative activities of the demonstration the following should be mentioned:—

1. In six years of demonstration the general death-rate has been reduced 16 per cent., the infant mortality-rate has been reduced 50 per cent., the tuberculosis death-rate 53·6 per cent. (the rates being corrected for non-residents and certification errors). While a reduction in these rates may have taken place anyway, or other factors were responsible, attention is invited to the fact that the death-rates in the towns about Framingham which were selected as control towns have experienced only slight reductions in the tuberculosis death-rate.

2. The examination of a representative population indicates that about 1 per cent. is suffering from active tuberculosis and an additional 1 per cent. from the disease in an inactive form. This corresponds to about ten active cases for every annual death in an average community. Therefore, in a city of 100,000 people there are probably 1000 cases of active tuberculosis. This is a percentage which has been substantiated by my own tuberculosis examinations of 174,000 American soldiers during the World War. Similar surveys in civil and military groups have given approximately the same percentage. (Of the first million American soldiers examined for military service in the World War 0·873 per cent. were rejected because of tuberculosis.)

3. These demonstration figures may well serve as a guide as to the percentage of tuberculosis which should be reported in a community. When the demonstration started at Framingham there were only 27 known cases of tuberculosis under care. The average ratio of reported cases to deaths was 3 to 1. After intensive search several hundred cases of tuberculosis were found and the ratio of reported cases to deaths was raised to approximately what it should be—namely, ten cases for every death. This means that a city with 100 deaths a year from tuberculosis should have reported approximately 1000 cases of active tuberculosis annually.

4. The number of cases requiring hospital or sanatorium care has been found to be one or two for every annual death in the community. Consequently a community should provide at least one, but preferably two beds for every annual death. One may estimate that about 42 per cent. of the total active cases under observation during the year will require institutional care. This will include, of course, many short stays in sanatoria or hospitals for educational and hygienic purposes.

5. In the beginning of the demonstration Framingham was equipped with a tuberculosis dispensary with a part-time nurse and medical attendant at the clinic. There was also an anti-tuberculosis society doing some educational work. This may be considered an average equipment for a city of 17,000 people. With this organisation as stated, the ratio of reported cases to annual deaths was 3 to 1. It is evident, therefore, that the average community reports little more than half the cases of tuberculosis and probably most communities report only about one-third. Consequently no effectual campaign can be waged against tuberculosis when only approximately one-third of the cases are under care, while two-thirds remain uncontrolled and potential sources of infection. This means that an efficient case-finding plan is necessary to bring the unknown half or two-thirds under supervision. In Framingham a sickness survey carried out by insurance agents and nurses disclosed some new cases after the health survey had been made. However, when practically the same area was canvassed and the residents given a thorough medical examination, nine times as much tuberculosis was found. Therefore, it is felt that routine medical examinations are necessary.

This can only be accomplished by means of an educational programme, which would have as its basis the evidence that in an average community about 90 per cent. of the population are infected with the tubercle bacillus, and of this 90 per cent. infected probably 2 per cent. have tuberculosis in an active or arrested state, but 10 per cent. will eventually die of the disease. Accordingly, the educational programme must teach how infection takes place, how children and others must be protected from massive infection by controlling open cases, improving general sanitation, and by the pasteurisation of milk-supplies. The educational programme must also teach that many cases can recover by proper institutional care, and there must be instilled into the community the idea of annual thorough medical examinations, which may be done at the clinic or by the family physician, with the help, if necessary, of the clinic, or consultation service, or by the factory or school physician, in the case of industrialists and children. It has been estimated that one factory or school physician is required for every 3000 individuals. An adequate nursing service must be provided also, of at least one nurse for every 2000 or 3000 people, to do infant welfare, school, factory, and home nursing, and follow up arrested cases of tuberculosis.

6. The consultation service is perhaps the most important single measure developed in Framingham for the discovery of tuberculosis. In addition to the foregoing, adequate institutional equipment, community organisation, and legislation are necessary.

It will thus be seen that tuberculosis in Framingham is being brought under control, and if these same methods could be applied to the entire United States it would mean a saving of 80,000 lives a year or more than were lost by the United States in the World War. It would prevent untold suffering and poverty, and when one considers the economic value of a human life, it is clear that, measured in the terms of money alone, the programme would mean a saving of millions of dollars annually.

Fundamental to the success of such a demonstration is the sympathetic coöperation and support of the local medical profession as well as the community in general. There must be created a strong sentiment for health work. The demonstration should be thoroughly grounded in the life, public affairs, and institutions of the community. It should show what scientific medicine is and what health movements are, and it should not permit itself to be regarded as a strange something, imported for the purpose of destructive criticisms and exposure of official and non-official agencies. Much of the credit for the success of the Framingham demonstration is due to the highly efficient service of its executive officer, Dr. D. B. Armstrong. The willingness and desire on the part of Framingham to develop and support an adequate health programme is reflected by the increased expenditure for health from 40 cents when the demonstration began to 2 dollars and 35 cents per capita last year.

Aside from local manifestations of benefit from the demonstration, its influence has been national in scope. It has stimulated scores of American communities to adopt new methods for discovering and caring for tuberculosis, as well as for infant welfare work. It has brought about the splendid big Millbank demonstration, which is applying the Framingham data to an entire county in New York State (Cataraugus), to a city of 175,000 (Syracuse), and to a district in New York City having a population of 216,000, and fairly typical of Greater New York City as to age-grouping, race stocks, birth- and death-rates, economic, social, and industrial conditions.

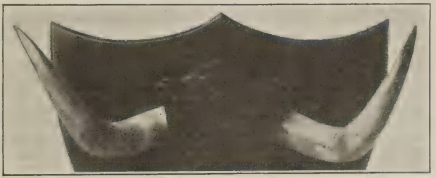
While the Framingham demonstration was primarily on tuberculosis, it has been very broad in its character. It has contributed to better health administration, better recreational facilities, better industrial relations and conditions. It has, in short, not been merely a medical demonstration; it has been a health and social demonstration to promote general healthfulness of the population at large, to prevent disease, reduce mortality, increase productiveness, and promote happiness.

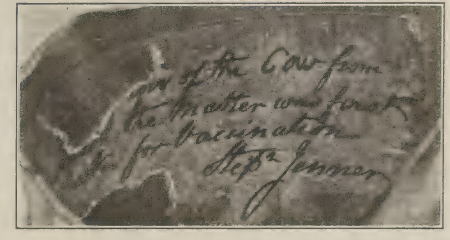
HOW CONSTANTINOPLE WAS CLEANED UP IN 1922.

IN the *Journal* of the R.A.M.C. for May Captain R. McKinlay tells the story of the sanitary difficulties which faced the Allies at Constantinople in 1922, when he was the executive officer of the Inter-Allied Urban Sanitary Commission, of which the British D.M.S. was president. Of the Inter-Allied Maritime Sanitary Commission the president was a French medical officer. The health of the city was a joint responsibility of the municipality and the Government, both near bankruptcy, unable to pay their staff, and so getting inferior service. The Turkish doctors, whose month's salary, long in arrear, was less than a skilled artisan in England gets every week, gave at first an impression of lethargy, but when they found themselves employed by people who took a real interest in their work and their welfare they worked well. The actual sanitary conditions were deplorable; water was insufficient in summer and bad (*B. coli* in 0·5 c.cm.), and people made it worse by dipping it out of main conduits in buckets. There was no conservancy; refuse was just cast out into the street. It took the Allies a year to get the city cleaned up, but by that time the inhabitants had found it cheaper to use sanitary dustbins than to pay fines. There were almost no drains, and those there were were badly built of brick, leaking and untrapped, and to these conditions the residents had learned to accommodate themselves, for "even in some of the best houses one is met by an intolerable odour, apparently not noticeable to the inhabitants." The scourges of Turkey are supposed to be three: tubercle, malaria, and venereal disease; how these were dealt with may be read in the paper. The overwhelming problem of Constantinople has been the refugees; groups amounting to over half a million are enumerated. They swelled the myriads of the prostitutes; "semi-starved and filthy, this vagrant population scattered vermin, often infected." This paper should be read in full for the graphic picture which it gives of sanitary problems in the Near East.

JENNER RELICS: THE HORNS OF THE FIRST COW TO SUPPLY VACCINE VIRUS.

AN interesting relic—namely, the horns of the cow from which the lymph was first taken for vaccination—is described in *Berrow's Worcester Journal* of May 24th, and by the courtesy of Mr. G. A. Turner, of Anderson and Virgo's Dispensing Establishment, Worcester, we are able to give illustrations of the horns. These were purchased from a furniture dealer of Barbourne, whose father has stated that the horns had been in the family for upwards of 80 years, and that they were bought from the grand-nephew of Edward Jenner, Mr. Stephen Jenner, in whose handwriting is the label on one of the horns. Mr. Turner has made exhaustive inquiries as to the history of the horns and has collected much evidence which, incidentally, includes a photograph of the son of Mr. Henry Phipps, of Berkeley, the first man who was ever vaccinated, and a photograph of the house where Jenner lived. He has verified the handwriting of Stephen Jenner, who was one of the attesting witnesses to the will of the discoverer of vaccination, and the signature is also confirmed by Mr. Scott, solicitor, of Gloucester, whose firm have acted for the Jenner family for a century. It may be noted that among other things which Mr. Stephen Jenner sold to the furniture dealer were some sketches in water colour of fresh-water fish said to have been drawn by Edward Jenner. There does not seem to have been any reference to these in the collection of Jenner relics sold at Messrs. Sotheby, Wilkinson, and Hodge's some 18 months ago (THE LANCET, July 29th, 1922, p. 260). It may be added that in the pathological department of St. George's Hospital there is a cow-hide which bears the inscription: "The skin of the cow from which the first vaccine matter was taken by Dr. Jenner. Presented by his son, October, 1857," and it is suggested that presumably the horns shown in the photograph belong to that hide. There is also in the Royal College of Physicians of London a horn which is stated to have belonged to a Jenner cow, the inscription being: "The horn of a cow given by the benefactor of man, Dr. Jenner, to his friend Sir John Fisher, and presented to this institution in 1813."





PUBLIC HEALTH IN NEW ZEALAND.*

THE report on Public Health in New Zealand during the 12 months ending March 31st, 1923, states that the census population in April, 1921, was found to be 1,218,913 (not including 52,751 Maoris); and that the mean population for 1922 (also exclusive of Maoris) was estimated to be 1,251,895, showing a percentage increase on the previous year of 2·29. The birth-rate (23·17 per 1000) was lower than in any year previously recorded except 1919, when it was 21·54 per 1000; though the *number* of births (29,006) was greater than in any year except 1920 (29,921). It may be presumed that these numbers and ratios refer to the calendar years mentioned. The infant mortality (under 12 months of age) shows a most marked and progressive improvement; in the decennium 1901–10, the ratio varied from 61·6 in 1909 to 88·8 in 1907; for 1911–20, from 45·3 in 1919 to 59·2 in 1913; in 1921 it was 47·8; and in 1922 41·9, the lowest on record.

An Epidemic of Enteric Fever.

There was no special incidence of infectious disease during the 12 months except an outbreak of enteric fever at Mount Albert, a suburban borough adjoining Auckland city, with a population of 12,500. The borough has its own water-supply from "a spring tapped at the bottom of a well which passes through volcanic scoria rock. . . . The catchment area . . . covers the slopes of an extinct volcano about 400 feet high . . . . A few lava streams come from the hill, and the spring is probably an old water-course, flowing from the hill, but covered with lava and scoria ash. These scoria beds vary in depth, being several hundred feet at the actual cone, but thinning off to nothing at the edges of the volcanic area. The stream forming the water-supply at Mount Albert is deeply covered throughout the catchment area. The lava beds are much broken and fissured . . . . It is difficult in such country to know what the actual catchment area is, as springs flow out from the cone in various directions; but on the possible catchment area there are now about 1000 houses, most of which have been built in the last five or six years." When the spring was first used about 12 years ago there were few houses on the catchment area and the water was very pure, both chemically and bacteriologically. The houses have increased in number; there are no sewers, drainage soaks into the very porous scoria soil, dumps being dug for the purpose. "As might be expected, this increase of population on the catchment area has been a source of anxiety to the Health Department, and a watch has been kept on the purity of the water for some years. Warning of diminished purity was sent to the Borough Council in 1913, but the water was not in such a condition as to cause serious alarm till November, 1921." The chemical and bacteriological analyses were, shortly, in January, 1921, albuminoid ammonia, 0·0023; chlorides, 3·1; nitrites, nil; nitrates, 0·43 per 100,000; oxygen absorbed in four hours at 80° F., nil; colonies on gelatine at 22° C., 49; on agar at 37° C., 24; *B. coli* not present in less than 5 c.cm. In November, 1921, *B. coli* was found in 0·1 c.cm.; colonies on gelatine, 127 per c.cm. (agar colonies not stated). The council were warned that the water was no longer safe, and chlorination was carried out; the smallest quantity containing *B. coli* was then (December) found to be 50 c.cm. The council reduced the amount of chloride added on account of complaints as to taste, and in March the medical officer recommended that it should be increased. Up to April 7th seven cases of typhoid had been notified in the whole metropolitan area, and there was nothing suggestive of an epidemic in any part of the Auckland district. On the 8th the first case of the epidemic in Mount Albert Borough was notified; on the 10th *B. coli* was found in 0·01 c.cm. water from the pump well (apparently at the Avondale Asylum); a number of cases of "gastric influenza" were reported in Mount Albert district. On the 13th the reservoirs were chlorinated and the mains flushed, and the city water then turned on throughout the area. On the 17th the inhabitants supplied from Mount Albert Borough station were warned to boil the water, and the public schools closed, as it was not possible to prevent the children from drinking unboiled water from the school taps. The progress of the epidemic was as follows: from April 3rd to 10th, one case; from April 10th to May 22nd the cases week by week numbered 23, 59, 35, 17, 11, and 5 respectively; there were four cases in the week ending June 5th, and one case near the end of the month. The cases numbered 156 from April 3rd to June 30th; and in addition to these there were 60 cases at the Avondale Asylum, commencing in the first two weeks of April. The total cases during the epidemic therefore numbered 216. The deaths appear to have been 14 in Mount Albert District and 17 in the asylum. The "spot map" referred to on p. 21 as showing "very conclusively how markedly the area supplied from the Mount Albert pumping well has been picked out by the incidence of the typhoid cases" is unfortunately omitted from the report. Otherwise this account of the typhoid outbreak and its causation, by Dr. R. H. Makgill, acting medical officer of health, Auckland, is most complete and convincing. "It is interesting to learn from the Government bacteriologist that infection was not confined to one organism of the enteric group, but that typhoid and both types of paratyphoid infection were detected. This is suggestive of a fairly widespread state of pollution on the catchment area."

Child Welfare and School Inspection.

Considerable progress has been made in regard to the important subject of child welfare; public lectures and demonstrations, addresses to teachers and midwives, mothers and young women, have been well attended. The average infantile death-rate for the whole Dominion has been reduced from 47 per 1000 births in 1921 to 42 in 1922, the lowest on record. "The Plunket Society has become practically part of the work of our hospitals." The Plunket nurses subsidised by Government have been increased from 60 to 71. Infantile diarrhœa and enteritis, that formerly killed from 10 to 20 babies per 1000 births, have fallen to three deaths per 1000; at Dunedin the mortality from this cause, which was 25 per 1000 in 1907, has been under one per 1000 for the quinquennium; at Christchurch the ratio has fallen from 45 to 3. Dr. Truby King, director of child welfare, remarks very forcibly that "it is much cheaper and easier to rear babies and calves rightly than wrongly," and quotes the aphorism of Socrates: "The beginning is the most important part, especially when we have to deal with anything young and tender." School medical inspection has been carried out under Dr. E. H. Wilkins as director, and Mr. T. A. Hunter as director of dental hygiene. Among 34,382 children examined 88·34 per cent. were found to have defects; defects other than dental were found in 60·40 per cent., dental decay was present in 67·16 per cent. Postural and structural deformity of the trunk and chest (26·03), enlarged cervical glands (11·25), enlarged tonsils (11·23), subnormal nutrition (7·41), and goitre (6·20) were the chief abnormalities detected. Vision was defective in 3·18, and hearing in 0·79 per cent. of the children. In the treatment of goitre with salts of iodine the results have been encouraging, about half the cases having derived considerable benefit. The school nurse is warmly welcomed by the majority of parents, but a much larger number of nurses is required.

Hospitals.—Native Population.

At the five hospitals and sanatoriums scattered over New Zealand a total of 1495 patients were admitted during the 12 months, April, 1922, to March, 1923; these, added to the 451 present at the beginning of the period, make a total of 1946 treated, the daily average present being 432; 1007 were cured or relieved, and 59 died. The Maori population (52,751) shows an increase of 2975 over the previous census of 1916. The proportion of females to males has risen from 832 per 1000 in 1891 to 890 in 1921; there are now 23·6 Europeans to one Maori. All the Maori health councils are in working order except those in South Island. The health of the native population shows an improvement over that of the previous year, "due in no small measure to the activities of the Maori health councils, under guidance of the native nurses and inspectors."

HEALTHY SOUTH AFRICA.

Mr. R. Gwelo Goodman is showing at the Royal Institute Galleries a record of ten years' painting in South Africa. It is a very interesting and varied show, and may be commended to medical men with an interest in a country which has so much to offer to health-seekers. The purity and clearness of the air and the generous sunshine are evident from the presentation of local detail in the distances of these fascinating pictures.

IS A "DENTAL WHO'S WHO" WANTED?

A SUGGESTION having been made that a "Dental Who's Who" on similar lines to "The Medical Who's Who," confined to licentiates and graduates in dental surgery, would be welcomed, the Grafton Publishing Company is inquiring to what extent the dental profession would be willing to coöperate before committing themselves to the heavy expenses involved in bringing out the first edition which probably could not be issued under 15*s.* 6*d.* It would be revised and published annually. Should the replies received by the Company at Chichester House, Chancery-lane, London, warrant the undertaking, a "particulars form" will be forwarded in due course.

Huxley Memorial Lecture

ON

BIOCHEMISTRY:

ITS PRESENT POSITION AND OUTLOOK.

Delivered in the University of Birmingham on May 29th, 1924,

By F. GOWLAND HOPKINS, M.B., D.Sc.,
F.R.C.P. Lond., F.R.S.,
PROFESSOR OF BIOCHEMISTRY AT THE UNIVERSITY OF CAMBRIDGE.

Mr. Principal, Ladies, and Gentlemen,—Let me first express my appreciation of the high honour done to me by the invitation to deliver this Huxley Memorial Lecture. The great English scientific worker and writer whom we commemorate did not in his own person contribute to the branch of knowledge which we are to consider, but it is a pleasure to know —as I do know—that in his later years he took much interest in it and believed in its importance.

The effective and continuous application of chemical methods and chemical thought to the problems presented by living plants and animals began somewhat suddenly when the nineteenth century was already well advanced. Such effective applications were first due to Justus v. Liebig, who as a biochemist seems to me to have had no predecessor in any sense that is real. Biochemistry as a body of knowledge owes, I think, almost nothing to ancient thought. The keen edge of the Greek intellect scarcely touched its particular problems as they now present themselves to us, for the sufficient reason that it possessed no data which would suggest that the problems, as we view them, even existed. The conscience of the historian of knowledge may, it is true, lead him to point to the iatro-chemists of the sixteenth century as predecessors of the modern biochemist; but if we do not let piety submerge our honesty, we must, I think, admit that the interest with which we read the outpourings of Paracelsus, and even the saner teachings of Van Helmont, is the kind of interest which attaches to the precocities of childhood. Such men, it is true, had intellectual predilections which may make them prototypes of the modern biochemical inquirer. Paracelsus, for instance, was, as Michael Foster said, "a chemist to the backbone," and he believed that through chemistry medicine was to become rationalised. But from his equipment facts were sadly absent and his teaching in consequence was sterile. Real appraisement, devoid of that sentimentality which often gives bias to history, will, I think, compel us to admit that there is no continuity between the thought of these so-called iatro-chemists and modern thought concerning biochemical phenomena.

The Birth of Biochemistry.

It must perhaps be always characteristic of a typical borderland science that it should be born with apparent suddenness. There comes, as it were, a critical moment when, one parent science having sufficiently developed its technique, and the other parent science having formulated certain suitable problems, a union of the two becomes fertile. There must be a certain degree of maturity indeed in both parents before the new science can appear. In the case we are thinking of it is fair to say that biology waited for chemistry. The seventeenth and eighteenth centuries were barren in respect of what I have called effective application even of the available chemistry to the available biology, and the same may be said of the first third of the nineteenth. Doubtless there are names belonging to these years which the historian aiming at completeness would register as worthy of mention, and among them he would include the truly great names of John Mayow and Lavoisier. The work of these two laid once for all the solid foundations of knowledge concerning respiration. They might, indeed, be classed as predecessors of Liebig in the irrefragable proofs they brought forward that the methods of the laboratory yield rational results when applied to the animal body. The work of Lavoisier indeed links up directly, though upon limited lines, with that of the late nineteenth century, which finally showed that the body is a seat of manifold combustions and as such obeys the first law of thermodynamics. Lavoisier, however, did not give the impulse which led to the development of modern biochemistry. His thought with regard to living beings was confined to an aspect of affairs which, however important, was limited. Where the chemical properties of the living tissues were concerned his thought was undeveloped and detached. If we define biochemistry as the chemical study of the material basis of life in its dynamic relations, then it was, I think, Liebig who really initiated the study. From Liebig's time (say from 1840 onwards) progress in biochemistry has been real and quite continuous, though, strange to say, the fact is not always recognised even in scientific circles. In this country at least one often meets with the naïve belief that biochemistry as a line of inquiry worthy of respect is brand-new—a product of the present century. This is partly perhaps because it has only recently received its now accepted, but not very attractive, name as a distinct branch of science. There are other and more interesting reasons to which I must refer.

It is unfortunately the case that, until the beginning of the present century, English work did painfully little to advance the subject. There was less interest in it here than in any other country of importance, and this even in the case of professed physiologists and biologists, and quite certainly in the case of pure chemists. In Germany and in Scandinavia much work was being done even 50 years ago, and Slavonic names have always been prominent in the literature. The schools of Hoppe Seyler, Hofmeister, Nencki, and Hammersten were centres of highly productive activity. One of the earliest and most important of the special journals devoted to biochemistry—Hoppe Seyler's *Zeitschrift*—began its existence only two years after Liebeg's death, and its pages from the first illustrate the continuous growth of highly significant knowledge. It is noteworthy, however, that the votaries of the subject were long peculiarly isolated, and had but a small audience. It is not without interest to discover why this was so. Liebig's earliest days saw, of course, the beginning of modern organic chemistry as well as that of biochemistry; indeed, at first, it was interest in the latter which stimulated work at the former. But the very success of early efforts in the chemical laboratory proved to be somewhat fatal to biological interests. The classical case, for instance, of the synthesis of urea by Liebig's intimate friend and associate—Wöhler—while it of course had the profoundest significance for biochemistry, providing indeed its very charter as a rational pursuit, carried with it the germs of something exceedingly inhibitory. The excitement caused by the proof that organic compounds could be made in the laboratory, and the extraordinarily rapid growth of the art of synthesis led the chemist to make a fascinating world of his own composed of molecules made by himself and not by Nature.

Its Early Neglect.

Biochemistry thus was scarcely born when the work and thought of the qualified chemist became divorced from the living plant and animal, and it is only now that his interest in them is re-awakening. Had not this divorce existed, the history of biochemistry during the last 50 years might have been very different. That physiological and biological thought for a long period of years made relatively little use of accumulating biochemical data was doubtless also due in part to preoccupation. Great advances were being made on lines which made no call for chemical data, and there was for all biologists occupation in plenty without the need of overcoming that inertia which is felt when the language, methods, and special conceptions of an accessory science must be acquired. But in the case of the biologist there was, I think, another reason for some lack of sympathy with biochemical effort. There was for a decade or two a pretty general feeling, which some minds still retain, that in biological phenomena chemical facts, though doubtless to be considered, are of superficial and largely technical import. Thus, while the borderland between chemists and biologists was being assiduously cultivated by at least a few devoted workers, for quite a long time very few indeed of their neighbours on either side looked over the border. Traffic across both borders is now setting in, and biochemistry is, I think, gaining sympathy and understanding from many chemists and biologists. I hope before long it may obtain them from all of them.

Sympathy and understanding from the lay public are, in a sense, not essential for scientific progress, but I am sure that most investigators would welcome, and be the better for, a general recognition of the fact that they are working for the public weal. It is certain that the lay public has not yet understood biochemistry, though the magnificent endowment that the subject has just received at Cambridge seems to show that men of affairs are open to conviction of its importance. But that the subject has hitherto had less public understanding than, perhaps, any other branch of applied chemistry is not surprising. The public relies on the lay press, and the press only notices in science what is sensational or of obvious practical import. Biochemistry has seldom, if ever, accomplished the former, and its practical applications have in the main been lost in what are for the laity the mysteries of medicine. But, to say the truth, biochemistry in the matter of public understanding only shares the fate of other biological science. Since it was startled by Darwin and by the pen of Huxley, but later forgot its alarms, the public has been apathetic where biology is concerned. The triumphs of pure chemistry and of modern physics are not unknown to it and represent its conceptions of the progress of science. Yet modern biology has, for those with ears to hear and eyes to see, triumphs scarcely less than those even of physics. I cannot yet claim this for biochemistry; but it can be claimed, say, for recent cytology, for certain aspects of genetics, and for that remarkable pursuit which has become known as experimental zoology. It is a pity that so many highly educated individuals know so little of the remarkably significant facts that have been won in these regions. But biological science has also great economic importance, and that fact the general public should at least be made to know. So great is that importance that I feel all should be grateful to your Principal, who has recently used his influence and his eloquence to urge it upon those who wish well to the Empire.

Liebig and British Apathy to Scientific Research.

To convince the more practically minded of the English people of the importance of scientific knowledge is proverbially difficult. Face to face with this indubitable circumstance, Liebig developed a line of thought which seems to me so interesting that I will risk a little of my brief time to tell you of it. His pioneer studies in scientific agriculture (essentially biochemical in character) had produced much effect in Europe generally, but in England little or none. Here among our agricultural authorities there was nothing but disbelief or indifference. This fretted the mind of Liebig almost beyond his bearing. He set himself in characteristic German fashion to probe deeply for a cause, and he came to the extraordinary but, for him, quite clear conclusion that the apathy of the British farmer was due to the influence of Francis Bacon of Verulam! He traced parallels between what he read in the *Journal of the Royal Agricultural Society* and what he discovered in the works of Bacon, and gained the actual conviction that the spirit of that high priest of the inductive method stood between British understanding and German biochemical science.[1]

It is pathetic to realise that in spite of this laborious research into the causation of British apathy Liebig failed to combat it, and I fear that to this day his name is associated in this country with his extract of meat rather than with his truly great pioneer work in organic chemistry and biochemistry. I certainly do not share Liebig's strange obsession. I do not fear that the spirit of Francis Bacon will stand between me and my audience on the present occasion while I plead the cause of the subject. I have only to convince you that its methods yield significant data. My first intention, however, is to urge that biochemistry, being *par excellence* a borderland science, is for that very reason a fit meeting ground for many minds. I think the biologist should come to it because it endeavours at least to elucidate what must always be a fundamental question in biology, the physico-chemical nature of living material wherever found. I think that even the physicist, and, certainly, the pure chemist should, sometimes at any rate, cross the border—shall I say?—for refreshment and change of outlook. The chemist, at least, if he desire to survey the chemical field as a whole, must include in his survey the events which happen in the living cell. Nowhere else can he learn how complete the *organisation* of chemical events may be. The living cell, of course, is a field in which the influence of the colloid state, of surface activity, and of directive catalysis is displayed to the highest degree, but all of those related characteristics have, as their special and most significant result, the organisation of multifarious reactions into a unified, active, dynamic system. It is, as I have said, this organisation that the chemist meets nowhere else, and unless he bears in mind that the capacity of such an organisation does exist in the scheme of things his thoughts concerning chemical phenomena as a whole must be incomplete. The claims of biochemistry upon medical thought will form the theme of a later section of this address.

The Attributes of Biochemistry.

Before attempting to appraise the present outlook in the subject I would like to say a few words about some general attributes which attach to it as a pursuit. Let me first confess that although I have rightly claimed that for three-quarters of a century the progress has been continuous and real, and that what it offers to the inquiring mind is already of much importance, yet it represents what is still an immature body of knowledge. This is why I began by insisting upon the shortness of its history. Its votaries have till lately been few and their task has been heavy, and, to say the truth, because it is a borderland subject it calls not alone for the interest for which I have already begged, but for the practical help of workers with diverse qualifications. If it calls for recruits it must be able to promise careers, and this I find at the moment it is able to do.

Biochemistry has some special attributes as a calling. As a branch of applied chemistry it trenches more nearly upon philosophical prejudices than other branches. It comes indeed rather nearer to these than other branches of biology, for it seems to treat living matter with no more respect than we accord to dead matter. Can chemistry with the help of physics rightly describe systems which, at least in their higher developments, seem to become inevitably associated with the mysterious phenomena of consciousness? This reiterated question must still be asked. Not a few still think it presumptuous to pretend to such descriptions. They hold that they can at best be only equivalent to description of the play of *Hamlet* without the prince. I must, of course, not stop to put the case for vitalism or mechanism, and I have only strayed into this thorny but much-trodden path because I think this particular attribute of biochemistry does appreciably affect the atmosphere in which its work is done. The thoughtful investigator is not always content to feel that utility alone justifies his efforts. He wants to conceive of some final if ideal goal. A young investigator may at moments have his doubts, but never when his research is making progress. Then, whether his tendencies are towards monism or dualism, or towards suspension of judgment on such matters, he is happy because he sees his work is real. Anyone who applies chemical and physical methods to the study of an organised system such as the living cell, and, perforce, deals with it piecemeal and from isolated aspects, must, of course, remember all the time that his data lose meaning if he does not in his thoughts relate the parts to the whole. The idea of "purpose" then creeps in, but it need not become a preoccupation. Abstract science has no such preoccupations, but it must be admitted that when a self-regulated system comes objectively before us it is difficult not to think that purpose controls its organisation. The purpose may be there, but, if so, it is surely not confined to biological systems. If a human mind familiar with the present scheme of things, and conceiving of no other, could have watched the evolution of atoms it would have seen purpose in the progressive reconstellations of electrons. Indeed, atomistic physics in its present endeavour to describe organised systems instead of dealing with abstract atoms comes nearer than before to the biological method of thought.[2] If a complete dynamic description of the living cell should ever become possible, the chemical facts, so far from being of superficial importance, must in any case form a highly essential part of that description. The exceptional nature of the materials with which it has finally to deal, and the fact that these materials are of real interest only while they still exhibit all that instability which represents life, introduce technical difficulties which constitute a second characteristic of biochemistry. Its earliest endeavours, of course, were mainly directed to isolating individual substances from the plant and animal with the intention of determining their constitution. To this endeavour there was early added (in the case of animal biochemistry) a study of what may be called the balance-sheet of the body, a comparison of income and outgo, and this permitted some, though very limited, conclusions as to the nature of the events in the body itself.

---

[1] Liebig: Ueber Francis Bacon von Verulam und die Methode der Naturforschung, München, 1863.

THE METHODS OF BIOCHEMISTRY.

It was indeed long the opinion of many that chemical studies could not attain to much more than this. How, it was asked, could information be obtained concerning events within living systems by methods which, at the moment of their application, must from their very nature upset the whole of the significant and essential relations? Yet it is a fact that biochemistry has so progressed that our studies of living tissues have become dynamic instead of static. By diverse methods, by taking advantage of one possibility here and another there; by realising the fact that individual reactions as such do not necessarily close when structure is destroyed; by learning how to arrest this or that process of change at its critical moment; by studying the activities of isolated organs while their life is artificially maintained; by noting the effect of the absence of this or that factor when it has been removed experimentally, or by disease or by inherited deficiencies; by noting what particular precursor can yield a given end-product; by using micro-methods of analysis so that they may be applied to the intact body without damage or hurt; by these and by a score of other (may I say) ingenuities in method, we are learning not only what chemical actions occur in living tissues, but the lines upon which reactions run, the stages through which they pass, the equilibria to which they attain. There is every reason to believe that without great difficulty we shall come to know the details of every one of the multifarious reactions which proceed, usually with great velocity, within a living cell. Far more remote is a grasp of their organisation which is the abiding characteristic of the cell. Personally, however, I do not believe that an ultimate understanding will call for knowledge of a category different from that which we are accumulating.

Apart from the instability of the systems which he is endeavouring to describe, the biochemist meets with another factor characteristic of his material: the importance, namely, of the infinitesimal. In living tissues a prepotent influence is exerted by substances present in concentrations which are minute. The necessity of adjustment to this circumstance, though by no means unknown to other branches of science, especially dominates the biochemical field and gives another special stamp to its study both on its theoretical and technical sides. Finally, biochemistry differs from other branches of applied chemistry in that it must at least occasionally employ living animals in its investigations. I might mention other characteristics, but I have said sufficient to remind you that the pursuit of biochemistry calls for a special equipment.

THE PRESENT OUTLOOK.

I will now pass on to some appraisement, necessarily brief and very imperfect, of its accomplishment and present outlook. I have already claimed that its data had reached real significance long before it attained in recent years to the status of a separate scientific discipline; but there is no doubt that its progress has accelerated of late to a degree which is striking. This is due in large part to efforts in its own proper sphere, but also, as would be inevitable in the case of any borderland science, to contemporary progress in the related sciences. Indeed, the factor of acceleration which would probably first occur to the mind of most is the coincident advance of physical chemistry. Biology, for instance, waited long for the data which colloidal chemistry is now supplying, and for such increased precision concerning factors which condition biochemical activity as may be illustrated by the arrival of the conception of hydrogen-ion concentration to replace the vaguer ideas of acidity, neutrality, and alkalinity. Such assistance has come, and is coming in increasing measure, from exponents of the more exact sciences, but the historian will note that these particular advances in physical chemistry of which I am speaking found their stimulus in biological needs and owed their initial success to biological workers. Biochemistry has, of course, also reacted to the progress of organic chemistry. Indeed, if one may make the point here—I have made it, too persistently perhaps, in other places—there is a tendency just now to ascribe to physico-chemical methods of study a too exclusive importance where the living cell is concerned. That the properties of colloids are of dominant importance goes without saying, but the multifarious organised dynamic activities in which the influence of molecular structure plays an unmistakable part are just as characteristic of life as the general behaviour of the colloidal apparatus in which these activities occur. It is true that the modern investigation of the behaviour of molecular structure at surfaces is breaking down somewhat the distinction implied in these remarks, but in any case the aid of the organic chemist in biochemical studies is needed as urgently as ever. It will be found, however, that much of the recently accelerated progress in biochemistry has been due to a development of its own technique. It was fortunate for the science that when some 15 years ago the need for new and especially for quantitative methods became urgent, a number of patient workers in America, in this country, and elsewhere set themselves to meet the demand with conspicuous success. This development continues, and of late has displayed itself especially in the multiplication of micro-methods of quantitative analysis, concerning the importance of which I will presently speak.

In illustration of the real significance of what has already been gained by biochemical study, I must be content to select a very small part of the available material. I will briefly discuss, almost in the form of a schedule rather than in that of a proper exposition, and perhaps without any logical sequence, certain aspects of the existing knowledge, each aspect being chosen to recall so far as possible a distinct line of endeavour with its results. I am inclined particularly to choose facts which emphasise the reality of the influence of molecular structure in the dynamic events of living matter, because I myself think that a realisation of this should form the very basis for biochemical thought. It seems to me that the influence of Ehrlich's "side-chain theory" has paradoxically made this reality unreal to some. That theory, though it served its turn, was itself an artificial and unreal application of structure considerations. It ultimately failed to satisfy, and many in rejecting it began to think in terms of adsorption, permeability changes, changes of dispersion and the like, and in these alone. This involves a standpoint quite as limited as that which the side-chain theory evoked. If I discuss facts which are familiar the circumstance will at least facilitate the brevity of treatment which is essential. I cannot deal with history.

---

[2] Compare Johan Hjort, The Unity of Science.

Certain Aspects of Our Knowledge.

Up to the very end of the last century our knowledge of the chemistry of those primary constituents of living tissues, the proteins, was slight and unsatisfactory. Then came, somewhat suddenly, very remarkable and rapid progress in that knowledge. That the effect of this upon the biochemical outlook would be extensive everybody realised at the time; but its effect, difficult to appraise in a few words, has been even greater, I think, than was expected. The protein molecule, though exceedingly complex in the details of its structure, proved relatively simple in type. We know the units—the amino-acids—of which its complex pattern is built up and the constitution of each of them—some 20 in all. The significant circumstance, however, from the standpoint of biochemistry proper is that the digestive processes liberate the units of structure from the protein complex, so that it is with these, and with each of them individually, that the body deals. Since the molecular structure of each is known, what may be called the true organic chemistry of protein metabolism became a possible study, and it has progressed remarkably. When protein is consumed, 20 distinct substances enter the body each with its own special attributes. We possess suggestive knowledge concerning the fate in metabolism of each one of them. We know already, at least in outline, the stages of change through which each passes while suffering decompositions or syntheses in the body. Only those who compare with the present outlook the existing views concerning protein metabolism before this chemical knowledge came can realise how great has been the influence of that knowledge. Our recently won grasp of protein chemistry has furthermore made the biologist understand that underlying the morphological differentiation of species there is chemical differentiation, of which the primary seat is in the proteins of the blood and tissues. "The material determines the form."

Choosing another illustration of successful progress in the chemical study of tissue constituents, I may recall how detailed is the knowledge we possess of those specific substances, fundamental in biochemical importance, which characterise the nuclei of cells. The pure chemistry of the complex nucleic acids has become remarkably complete, and highly detailed is our knowledge of the successive stages in their metabolism.

THE INFLUENCE OF MOLECULAR STRUCTURE ON BIOCHEMICAL PHENOMENA.

In illustration of how most extensive information has been gained concerning the equipment of the living tissues as laboratories I might call attention to the researches which have dealt with the chemical fate of foreign substances when introduced into the body. The pharmacologist in studying organic drugs determines the influence of molecular structure as it affects the tissues. In doing so, however, he cannot refrain from ascertaining how, conversely, the tissues deal with the molecular structure of the drug. On these lines, carried outside the limits of pharmacology, a body of knowledge has grown up which is greatly significant to biochemistry. But it is technical and I must not dwell upon it. Suffice it to say that the body proves able to carry out efficiently, though under its own exceptional conditions, almost every process that is familiar to the organic chemist; and as much in the body as in the laboratory the precise fate of a substance is determined by its molecular structure.

I am much concerned to show how little any quality that is "biological" or "vital" in living systems submerges the influence of molecular structure—that is, the influence of frankly chemical properties—in biochemical phenomena. In further illustration of this I may turn to what is now the familiar subject of the internal secretions. The discovery of these, due to the pioneer labours of English physiologists, gave a new charter to biochemistry by adding to the biological reality of its data. Everyone who thinks at all of such matters will realise that in so highly differentiated a system as the animal body agencies must exist to coördinate the activities of each organ with those of all others, else the system could not work harmoniously. Until about 25 years ago such coördinating functions were ascribed solely to the nervous system. Now we know that underlying the influence of the nerves there is chemical coördination. Many, and probably all, organs and tissues of the body, in addition to exercising their local functions, pour into the blood-stream secretions which, carried round by the circulation, help to secure harmony and balance in the body as a whole. The normal working of each tissue would seem to depend upon such contributions from almost every other tissue. Profoundly significant, and a remarkable justification for the boldest application of chemical methods and chemical thought to the functions of the body, is the almost inevitable conclusion from our present knowledge that all their secretions act because each contains a definite specific substance which induces or controls some physiological event, or some essential aspect of a physiological event, as the result of its inherent chemical properties.

If the specific chemical properties of a substance, and these in the case of an organic compound represent the results of a particular molecular structure, determine the occurrence of change in a physiological system, it must be because within that system the properties of molecular structure are also somewhere displayed. It may be the structure of molecules in solution; it may be molecular structure displayed at surfaces. In any case, the chemical lever calls for a chemical fulcrum. In one case at least we have a perfect knowledge of the molecular structure—and it is a relatively simple structure—of a substance which appears in the body with profound effect. The case of adrenalin, which has occupied the attention of hundreds of observers, has become so familiar, and its physiological and pathological relations have so held the field, that its significance to my particular theme may be obscured. Here we have a substance produced, mainly, at least, by a pair of small organs and circulating at any moment in extremely small amount, which controls some of the most fundamental adjustments of the body. I clearly must not stop to dwell upon its functions. For the very few who are not familiar with them I may most briefly state that its availability in average amount secures among other adjustments the proper regulation of blood pressure and all that depends upon this. If its supply fails the animal is incapacitated, while an increase prepares it for strenuous endeavour by raising all the functions required by such endeavour to the right pitch of efficiency. From the standpoint which I am asking you to take, the essential thing is that these striking effects are due to the qualities of a relatively simple chemical substance of which the structure is known and which can be made artificially. The adrenalin molecule is one of a group of molecules which exercise a prepotent influence in the scheme of things.

The Thyroid Secretion and Insulin.

Exercising quite different functions, but of equal significance, are other definite chemical substances each elaborated by a special organ of the body. I will refer to two only. The iodine compound produced by the thyroid gland as the result of its innate characters controls in some remarkable way the rate of chemical change in the tissues. It has been isolated, though its constitution is not yet accurately known. Insulin produced in the pancreas is again assuredly a perfectly definite chemical agent, though awaiting isolation. The necessity of a supply of this last substance for the proper utilisation of sugar by the tissues is a circumstance with which everybody here will have recently become familiar. You will observe that what is significant for my particular theme is not the details of the physiological events, but the facts of the potency displayed by definite chemical substances in the normal control of such events. The effects of chemical structure are not submerged in the "biological" or "vital." Moreover, the importance of molecular structure is beginning to be seen in the catalytic agencies which are contained in the essential make-up of each individual cell. We know at least that one universal constituent of living cells, because of its molecular properties, determines the occurrence of change. Its molecule contains a Thiol group and the substance, itself being autoxidisable, determines, though present in very low concentration, the occurrence of other important oxidations. Its mere presence secures that a constituent part of the cell system shall display dynamic properties. In a real sense, I think, this substance "glutathione" may be looked upon as a simple model of an enzyme. Enzymes themselves are, of course, the chief catalytic agents in the cell, and concerning their molecular structure we as yet know nothing. Our attention so far has been mainly directed to their colloidal properties, but however great the importance of these, we shall, I feel sure, ultimately discover that some element of structure, some active group, is the essential determinant of each enzyme's activity. When an enzyme has been isolated and its precise nature determined, biochemistry will have taken a great step forward, because although a great deal of important information has accumulated as the result of studying the kinetics of reaction as controlled by these agents, the enzyme had perforce in every case been impure when introduced. The actual mechanism of enzyme action is yet unknown, and will be until we can investigate the nature of the catalyst itself. The endeavour to isolate enzymes is proceeding very vigorously just now, and is not without promise of an early success.

The Physical Basis of Life.

The recognition of the existence of active specific catalysts within the cell and a belief in their manifold activity, together with some other advances, has modified in an important way views which were common in Huxley's time concerning the nature of what he called the physical basis of life—the material make-up of a living unit. We are ceasing to believe that the living unit is some sort of a giant molecule. The term protoplasm itself is, I think, recognised by most as representing an abstraction. The living unit is the cell, or if some simpler system, at any rate one of which the essence is that it is heterogeneous. There is no such thing as living matter in a specific sense. The criteria of life are displayed by systems in which catalysed reactions occur in a colloidal milieu. The special attribute of such systems from a chemical standpoint is that these reactions are organised, not that the molecules concerned are fundamentally different in kind from those the chemist meets elsewhere. If this kind of concept concerning the physical basis of life proves ultimately right, it is certainly more stimulating to chemical thought, and gives more justification for chemical methods of attack than the for ever elusive protoplasmic molecule. Certainly, intact living tissues would seem difficult enough to study by chemical means, but that solid information can be obtained about the events which occur in them, even without present technique, is well illustrated by the results of the studies of active muscle. It is, for instance, remarkable how satisfying is the present picture we possess, even though it be but a sketch, of the chemical events which are associated with the physiological events in muscular tissue.

As a last illustration of the significance of biochemical data I may adduce the growing knowledge concerning equilibria in the circulating blood. This constitutes already a chapter of exact science. It is based, indeed, upon the development of admirable methods. It covers the equilibrium changes between the blood and the alveolar air, between the blood and the tissues, and is concerned with the excretory functions of the kidney. It illustrates most remarkably the stabilising effect of perfect buffering in a fluid which constantly receives additions of acid or alkali without appreciable changes in the concentration of hydrogen ions. The properties of the hæmoglobin molecule as an oxygen carrier are so exceptional and remarkable, that I think no chemist's education can be complete unless he be fully familiar with them. I may point out further that the recent development of accurate micro-methods of analysis have enabled us to determine the amount of nearly all known constituents of the blood, organic and inorganic, on an amount of material which in each case can be got from a pricked finger, or at any rate upon two or three cubic centimetres. The effect of this or that factor upon the equilibrium between the blood and tissues can thus be determined in detail, and without inconvenience even to human subjects. A noteworthy body of knowledge is growing up on these lines which will influence both physiology and medicine.

My survey of the biochemical field has been so limited as to be almost trivial; but it is sure that nothing but the strictly limited could be attempted in a part of a single address. I have, to my regret, said nothing of the all-important phenomena displayed by the green plant, the very fundamentals of biochemistry. I have, again, not referred to the data gained from studies of the metabolism of micro-organisms. Yet in the case of bacterial chemistry much, if somewhat unorganised, knowledge has been gained, and, as you know, fermentation chemistry has of late made rapid strides. The lessons to be learned from the chemical behaviour of micro-organisms are indeed of profound importance to biochemistry as a whole. The science, like many others, has hitherto been studied too much in water-tight compartments. In one centre "biochemistry" means fermentation chemistry alone, in another medical chemistry alone. If now I am to turn to consider the future of the science I will start by saying that its future will be well served if it be taught, at least to a special group of students, as a whole. Metabolism—that is, the chemical dynamic of living things—to be understood must be thought of as a whole from its manifestations in a bacillus to its manifestations in man. So surveyed and thought about the subject becomes, as I have already claimed, a meeting place for many minds.

The Future of Biochemistry.

In a brief attempt to picture its future possibilities I cannot emulate the prophetic method of Mr. Wells, or the stimulating thought of my colleague Mr. Haldane. It would be, of course, easy enough to speculate, for example, upon a world in which biochemical synthesis replaced agriculture. Indeed, as soon as the constitution of three or four vitamins becomes known there is no reason, so far as we know, why we should not begin to set about the synthesis of a perfect dietary. Kindred speculations might easily occupy us, but something more sober may be more useful. Since, however, I have happened thus to touch upon the question of dietaries let me just state that, in my opinion, biochemical science will in the future yet have much more to say concerning the details of ideal nutrition. I think surprisingly more! Such details may not at present interest the laity nor even the practising physician. The less thoughtful are content to remember that humanity has rubbed along very well in respect of its nutrition by the help of its instincts and experience alone. It was indeed a feeling similar to this, and not, as he thought, the spirit of Francis Bacon, which really stood between Liebig's earlier teaching and the British agriculturist. The farmer has learnt a good deal since, but the above feeling is still in his mind, as it is in the general mind when, unwillingly, it reads of calories, proteins, and vitamins. The future world will, I think, take a different view. If industrialism increases while the available fertile areas of the globe steadily decrease, and that is the most likely outlook, mankind will best save itself by knowing all that can be known about the economies and the betterments which biochemical science alone can provide. Students of nutrition then work for the future. Nevertheless, I would not have you believe that what has already been accomplished in this domain is of no practical value to the present. Had I leisure, and were this the occasion, I could easily convince you to the contrary. But with regard to the immediate future of biochemistry let me only just say that in all the lines of inquiry just chosen for illustration, and in a score of others, progress is accelerating, for the happy reason that more qualified workers than ever before are now engaged upon them. The science has not yet won universal recognition from those sciences for which it is a borderland, but, as I have already said, traffic across the borders is setting in, I think, to the advantage of all For the main theme of this address is that biochemistry, because of certain attributes it possesses which I have already imperfectly indicated, is, perhaps, more than other borderland sciences, a fitting meeting place for many minds and for many university faculties; though because of other attributes it calls for special discipline and special equipment.

THE CLAIMS OF BIOCHEMISTRY ON MEDICAL THOUGHT.

I would now like, in a few words, to put a final consideration before you. It concerns the status of laboratory science, including biochemistry, as accessory to the progress of medicine. I do not wish to discuss the relations between the medically qualified laboratory worker and the clinician. These, after a period of adjustment, seem now to be most happy. The leaders of the English clinical world indeed officially recognise and superabundantly reward those who from the laboratory have made even the smallest contributions towards the progress of medicine, as I in my own person can testify. It is of the public I am thinking, but of the cultured public as well as the general. The public understands the aims and work of the practitioner and at bottom is deeply grateful for his services; but it has never really placed the laboratory worker. It is apt, perhaps subconsciously, to assume that medicine advances by experience alone. Now, it is no reflection at all upon the great art of medicine, nor indeed upon the clinical investigator, to claim that the great and sudden advances that have occurred in the history of modern medicine have been based upon knowledge first gained in the laboratory. Some would perhaps not agree with this statement, but I think most—and certainly the candid historian—will do so. Clinical observation laid, of course, the solid foundations of knowledge, and laboratory teaching cannot be accepted by the doctor until it has been proven and consolidated at the bedside; but rapid progress, revolutionary steps in advance, must nearly always begin in the laboratory. The reason is obvious. The clinician must in the main rely upon observation rather than experiment. This the public will be the first to recognise. Now the accumulation of knowledge by observation alone (the older method) must always be infinitely slower than the gain of new knowledge by experiment. Certain words of a great English clinical observer struck me when I met them long ago as significant. I have quoted them elsewhere,[3] but I should like to quote them again. The great English clinician, William Jenner, had been striving to convince his colleagues that typhus and typhoid fever are distinct in their ætiology. In this effort, though so entirely right, he was at first unsuccessful. "I considered, therefore," he writes in the preface to his book on fevers published in 1850, "that it was necessary to begin again *de novo* and consult only the voice of Nature—convinced that although the most intellectual might fail at first to comprehend her often ambiguous language, yet that her most humble votaries might, by patience and daily watching, by keeping honest record of every sound she uttered—by joining letter to letter, adding word to word, and line to line—at last spell out her meaning . . ."

Here in fine but almost pathetic terms we learn what the slow task of the observer must be. Jenner felt the ambiguity of Nature's chance remarks, but saw apparently no remedy save in the laborious recording of her spontaneous utterings and a painful effort at interpretation. Nature, however, can be taken into the witness-box and sharply questioned. Moreover, the questions can be so put as to admit of no ambiguity in the answer. That is the method of experiment!

Now the biological laboratory worker is usually at least as disinterested as his fellow-men. In general, perhaps, he craves less than most for public rewards. But he deserves public recognition as an honest citizen and should not remain unclassified in the body-politic. He has become as much an essential unit of the social organisation as any other worker. May I add as my final word that if he happens to be a biochemist, who in common with the physiologist and pathologist must at times employ living animals in his experiments, he may yet be as kind and honest in heart and soul as the best of his fellow-men, carrying out such experiments with the fullest sense of his responsibility to humanity.

A Lecture

ON THE

SENSIBILITY OF THE SKIN

IN RELATION TO NEUROLOGICAL THEORY.

Delivered at the Institute of Pathology and Research,
St. Mary's Hospital, London, on June 5th, 1924,

BY WILFRED TROTTER, M.S.LOND., F.R.C.S.ENG.,
SURGEON AND HOLME LECTURER IN CLINICAL SURGERY,
UNIVERSITY COLLEGE HOSPITAL, LONDON.

IN the physiology of the nervous system it is a very obvious proposition that the finer study of sensory function can be carried out only in relation to the human subject. Moreover, if such work is to have more than a very narrowly limited value, it must be concerned with the effects of lesions experimentally produced and observed in the conditions of the physiological laboratory. It was these facts which made the work of Head and Rivers in this field so immediately and manifestly important. This now classical contribution to neurology made available a new method of research, recorded a large body of observations which were the first-fruits of the new method, and enunciated a hypothesis bearing on the fundamental nature of peripheral sensation. The opinion may be ventured that in the ultimate estimation of this work physiology will come to apportion value to its various constituents in the order in which I have named them.

It is probable that no new method of physiological research has been less exploited by other writers than has that of Head and Rivers, and that no equally revolutionary hypothesis has been less criticised or confirmed by repetition of the original experiment. This may well be due to the justly authoritative status of its makers, as well as perhaps to the rather dry and recondite nature of the subject, and the exacting tedium of the research. It is nearly 20 years since their paper was published, and I am aware of only two attempts thoroughly to cover the same ground. The first of these was undertaken by Morriston Davies and myself, and its first results were published 15 years ago. It embodied the results of a somewhat prolonged study during which observations were made on seven different areas of sensory disturbance experimentally produced by nerve section and suture in one or other of the two subjects.

---

[3] "Science and the Nation." Camb. Univ. Press.

Our results, when compared with those of our predecessors, showed in the first place a certain general agreement as to the facts of observation; secondly, showed a divergence in regard to certain observations which we could not but regard as critical; and thirdly, they appeared when the utmost allowance for interpretation had been made, to be incompatible with the hypothesis of peripheral sensation at which Head and Rivers had arrived. I do not propose to trouble you with a critical examination of these divergences. Since, as it seems to me, they are not wholly to be explained as differences of interpretation, they can best be determined by further experimental evidence. The consideration of what additional evidence is now available would, however, be a digression from the limited subject I propose to deal with to-day. My intention is rather to make some comments on the hypothesis of Head and Rivers in its general neurological aspects, and then to indicate certain other considerations which seem also to be suggested by the facts.

THE HYPOTHESIS OF HEAD AND RIVERS.

It seems scarcely necessary to describe in detail so well-known a doctrine as that of Head and Rivers, but to avoid ambiguity I should perhaps remind you of its general features. According to these observers each cutaneous sensory nerve contains two systems of fibres which differ in function, in distribution, and in the rate at which they regenerate after section. One of these systems is concerned with what may be regarded as the less highly evolved forms of sensation (pain and sensibility to thermal extremes); it yields sensations of a peculiar intensity—usually disagreeable, tending strongly to produce a motor response, and having peculiarities of localisation; it regenerates readily and earlier than does the other system, and in distribution it is freely overlapped. The other system is concerned with what may be regarded as the more highly evolved forms of sensation (light touch and sensibility to intermediate temperatures); it regenerates less easily and more slowly than does the first system. When present and functioning in a given area of skin it inhibits the peculiarities of quality and localisation which sensibility would have if it were dependent on the first system alone. To these two hypothetical systems of nerve fibres Head and Rivers gave the exceedingly apt and attractive names of protopathic and epicritic respectively.

The main fact on which this hypothesis is based is that sensibility in an area of skin of which the sensory nerve is regenerating possesses certain peculiarities of which an intensification of quality and a certain displacement of localisation are the most characteristic. This fact is wholly incontestable, though it is not equally certain how constant an accompaniment of regeneration these peculiarities of sensibility are. They were certainly present in all the seven experiments in nerve section made by Davies and myself. Certain further and less definitely established observations are necessary for the support of the hypothesis.

When a cutaneous area is deprived of its nerve-supply, since the area of epicritic loss is greater than the area of protopathic loss, the central region which is deprived of both forms of sensibility must be surrounded by a margin which retains protopathic sensibility only. According to the hypothesis this intermediate zone, as it may conveniently be called, should possess a form of sensibility substantially identical with that peculiar sensibility characteristic of regeneration. This identity Davies and I were quite unable to confirm, and we found reason to regard the intermediate zone as a mere region of defective sensibility of all forms gradually increasing in depth from its margin inwards.

A further group of observations essential to the validity of the hypothesis is, first, that during regeneration the return of epicritic sensibility is greatly delayed, and secondly, that with this return of epicritic sensibility (e.g., sensibility to light touch) the sensibility of the area in which regeneration is occurring loses those characters of intensification of quality and displacement of localisation it formerly possessed. In neither of these essential requirements did our observations confirm those of Head and Rivers.

As I have already said, I shall do nothing here by way of critical discussion or detailed examination to enforce the bearing of these discrepancies of observation. They are mentioned only as they necessarily gave rise to the suggestion that the protopathic-epicritic constitution of the cutaneous nerves could scarcely be regarded as definitely established, and that possibly further consideration might afford at least an alternative method of regarding the facts.

When we take a general view of this hypothesis, it is difficult to guard ourselves from taking its compactness, its symmetry, and its self-consistency as in some way contributing to the proof of its validity. To yield to such an inclination is perhaps the most subtle and tempting fallacy to which neurological speculation is exposed. The history of science has shown time and again that these marks of a biological and especially of a neurological conception are often not merely irrelevant as evidence, but actually a ground of suspicion that the conception in question contains too large an amount of the abstract and the unreal. Indeed, it may perhaps fairly be said that the hypothesis of Head and Rivers has enough in it of essentially abstract elements to make a real difficulty to its being accepted as representing a neurological reality.

I do not propose to trouble you with any attempt to discuss this very difficult department of the theory of method, and I can only indicate one or two of the aspects of the hypothesis which seem to me dangerously abstract.

We are to regard the protopathic system as more or less definitely representing an evolutionary phase in which it constituted the sole sensory apparatus of the skin. The hypothetical primitive animal of this stage is thus supposed not merely to be without the power of appreciating intermediate temperatures and of localising contacts, but without the power of appreciating light touch. It is difficult not to regard such a conception as a highly abstract one, and very much out of relation with biological reality. There is, as far as I am aware, no biological evidence for regarding sensibility to light touch as less primitive than any other form of sensibility.

Again, one may mention the effect of the epicritic system in totally inhibiting the characteristic qualities of protopathic sensibility. It is suggested that both in the evolutionary process, and during regeneration in the individual, the mere appearance of epicritic sensibility neatly and absolutely effaces the very remarkable qualities of protopathic sensibility, which, however, remain merely concealed and ready immediately to reappear if the epicritic system is withdrawn. Quite apart from the question whether this is or is not an established fact of observation, the conception would seem to need the closest examination before it could be accepted as a definite neurological principle. Difficulties of this class may seem to be unimportant unless we constantly remember the vital need in all matters of neurological theory for realistic rather than abstract thought. I shall make no attempt to deal further with this aspect of the subject, however, beyond pointing out one assumption that seems to me to be made in the work of Head and Rivers, and to be of serious importance. It is taken for granted that all the consequences of division and suture of a nerve are what we may call physiological or normal, and that any peculiarities of sensibility in the affected area of skin are merely due to defects of nerve supply, and represent stages in the orderly return of function. These observers do not seem to have contemplated the possibility that section of a nerve may in itself be a serious pathological accident, the possible effect of which on the character of sensation might be worth considering. Even the most general consideration would seem to suggest that we are exposing ourselves to the risk of error if we assume that the local consequences of division and suture can be ignored, and that our sole task is to observe and record the regular and punctual return of function.

The Effects of a Nerve Section.

There are abundant and familiar facts pointing in a precisely opposite direction. In the first place, the restoration of function, even after the most careful suture of nerves, is notoriously uncertain and apt to be greatly delayed and incomplete. Secondly, the site of the division and suture of a nerve is the seat of pronounced activities which are readily observable histologically. These activities are partaken in by the nerve and by the surrounding tissues. On the side of the nerve there is at the proximal end an active outgrowth and ramification of the axis-cylinders which pour out from the cut surface in a veritable spray, and invade not merely the peripheral end of the nerve but the surrounding tissues as well. On the side of the tissues surrounding the divided nerve there is an equal activity, the tendency of which is to form a dense fibrous tissue that restrains the escaping axis-cylinders and protects the surrounding parts from unlimited invasion by them. These processes are seen in their highest development in the well-known bulbous end or "amputation neuroma" that always follows the simple transverse division of a nerve. Here are very well seen the extreme activity of the outgrowing axis-cylinders, and the very great density of the fibrous capsule with which the surrounding tissues defend themselves. It is so general a rule in pathology that disturbances of function precede any obvious alteration of structure in the affected part that it would be at least remarkable if these very pronounced structural changes had no functional counterpart at all.

That this activity is not, in fact, without effect on the function of the nerve is shown by the well-known sensory phenomena that follow amputations even in the total absence of infection of any kind. That the outgrowing axis-cylinders are subject to excitation in the amputation neuroma is made evident by the persistence of "phantom" limbs after amputations. The degree of this excitation is very variable. Sometimes it is very severe and the phantom limb is the seat of very painful and distressing sensations. More usually equilibrium in the neuroma is gradually established, and the persistent sense of the limb slowly fades. From facts such as these certain conclusions of general application seem to follow. First, it is clear that the division of a nerve, followed by however exact and aseptic a suture, must always be an important event in the neurological sense and one that gives rise to indefinitely great possibilities in the way of disturbed function. Secondly, the significance of such an event lies in the coming into contact of bare axis-cylinders with adjacent non-neural tissues, and the energetic reactions set up in consequence.

The occurrence of these reactions and the fact that they are capable of producing functional disturbances of the affected area, suggested to Davies and me the possibility that in this direction might be found some light on the marked peculiarities of the sensibility of recovering areas. Of these peculiarities, the most striking, and undoubtedly the most important, is the intensification of sensations. This character is in no way a hyperæsthesia, since the sensation may need an abnormally strong stimulus to elicit it, but is concerned entirely with quality. This intensified quality—which is most easily observed with pain and cold sensations—gives to the sensation a kind of explosive vividness and brilliance which constitute a wholly new experience. There can be no question that the intensification of sensation is the essentially significant fact in the phenomena accompanying regeneration.

The conception that the direct contact of neural and non-neural or, as we may perhaps call them, somatic tissues is always a significant event neurologically and capable of producing widespread functional disturbance, naturally led us to inquire whether in the nervous system in general such an occurrence is provided against as thoroughly as the hypothesis seemed to require.

The Insulation of the Nervous System.

Considered in the most general way, the nervous system is a collection of tissue the essential function of which is the capacity to act upon and be acted upon by the other tissues of the body. This character in one aspect is the power to stimulate and be stimulated by the somatic tissues, and in another aspect is an incapacity to tolerate direct contact with them—an inveterate and probably physico-chemical incompatibility with them. It is essential, therefore, that the qualitative difference between neural and non-neural tissues should be kept sharp, and, on the other hand, that contact between the two kinds should be absolutely restricted to points where interaction is necessary.

In actual anatomical fact such insulation is unmistakably traceable. In the case of the central nervous system the dura mater is the principal insulating medium, in the case of the peripheral nerves the neurilemma sheath. Every element of the nervous system is kept from contact with somatic tissues either by the dura or by a neurilemma sheath, and in this insulation there is no chink except those very restricted ones which allow of contact for functional purposes.

The function of the dura has generally been regarded as chiefly mechanical and supporting. Familiarity with its physiology and pathology shows its insulating function to be far more important. If a segment of cerebral dura is excised and the subcutaneous tissues of the scalp left in contact with the brain, a new segment of dura immediately begins to form in the gap and in a few weeks is indistinguishable from the old—that is to say, it has the same dense impervious substance and the same endothelial surface within and without. It is apparently formed by a reaction in the non-neural tissues from contact with the brain by a process perhaps similar to that by which contact with naked axis-cylinders leads to the formation of the amputation neuroma.

The cerebro-spinal fluid also posseses the neural characteristic of exciting dura formation. If the spinal dura is incised and the fluid allowed to escape into the tissues, it excites around it the formation of a sac continuous with, and in character indistinguishable from, the normal dura. This fact, that wherever cerebro-spinal fluid is a dura will form round it, explains the uniform failure of all attempts to drain the fluid of hydrocephalus into extra-neural regions. The size of the central nervous mass has necessarily involved its free penetration by blood-vessels non-neural in their nature. The more or less complete absence of neurilemma in the brain and cord has rendered necessary the insulation of these vessels to compensate for the absence of insulation of the individual nervous elements. This is effected by the exact enclosure of all vessels in the so-called perivascular lymphatics which from this point of view are seen to have a very definite and important function. When we see how precisely insulated is every somatic element that penetrates the brain or cord, it becomes clear that no general framework of connective tissue would be possible there, and we may infer that the neuroglial stroma of the central nervous system owes its existence perhaps less to its being in any special degree fitted for the mechanical support of nervous elements than to its being of neural origin and so able to exist in contact with active nervous tissues without reaction.

Outside the dura the insulating function is taken on by the neurilemma which is everywhere continued unbroken to the functional termination of the axis-cylinder.

PATHOLOGICAL CONSIDERATIONS.

It is possible to trace in pathological phenomena further evidence of the reality of what we may call neuro-somatic incompatibility and the importance of neural insulation. One very striking fact is the inaccessibility of the actual parenchyma of the central nervous system to certain drugs—for example, anti-syphilitic remedies. This fact, wholly unexpected as it was to ordinary physiological notions, is perhaps especially interesting in its bearing on principle, since it led to the invention of those extremely plausible abstractions para-syphilitic diseases. It seems scarcely possible to doubt that this ultimate impenetrability of the brain and spinal cord is an expression of the degree to which insulation is carried. Again, certain features in the behaviour of some intracranial tumours can only be explained when we grasp the depth of the incompatibility of neural and non-neural tissues. The dural endothelioma as regards the dura, the skull, and the scalp is capable of behaving as a typical malignant neoplasm with infiltrating spread and ulceration. As regards the brain, however, it is always benign; it may compress it and even become deeply embedded in it, but it never in any circumstances infiltrates the cerebral substance. The glioma, on the other hand, may infiltrate the brain substance, but though it may thin the skull by pressure, it never invades it. These growths thus show their essentially non-neural and neural origins respectively, and always remain true to type.[1]

Of pathological facts bearing on the importance of neural insulation those illustrating its breakdown are perhaps the most interesting. The ordinary neuro-fibroma bears a considerable resemblance in structure to the amputation neuroma, being made up of convoluted nerve-fibres embedded in a dense fibrous tissue. It seems reasonable to suppose that it is essentially of the same nature and owes its origin to an escape of axis-cylinders from their normal insulation as the result of the weakening of this by injury or disease. In Recklinghausen's disease the suggestion is strong that we have to deal with a widespread primary weakness of the insulating mechanism leading to multiple escapes of axis-cylinders, each "leak" producing the inevitable reaction in the form of a neuro-fibroma. Such neuromata are, of course, very much the most common in the peripheral nerves, but they do occur within the spinal canal and within the cranium. It is interesting to notice that those neuromata that occur inside the dura are not usually made up of the dense hard fibrous tissue met with elsewhere, but are usually much softer, more cellular, and apt to undergo degenerations and cyst formation. This is just the variation one might expect, since within the dura the reaction to an "escape" must be less vigorous and the available non-neural tissue capable of reacting to it very strictly limited in amount.

INSULATION OF SENSORY NERVE-ENDINGS.

In tracing the various mechanisms by which the insulation of neural tissues from the non-neural is maintained, we have not yet considered the state of affairs at the terminations of the peripheral nerves. Three conditions are found each of which has its special significance. The end-organ of motor nerve-fibres seems to be one of the regions in which some kind of contact between neural and non-neural tissues is allowed in order that the action of one upon the other should be possible. Thus we find that the neurilemma sheath of the nerve-fibre is continued into the sarcolemma of the muscle-fibre so that the two tissues are brought together while no other contact is permitted.

The second type of structure is that in which most of the ultimate branches of sensory nerves appear to end. With a good deal of variation in construction, and under many names which we need not enumerate, these end-organs have certain common features of structure. In general, we may say that all forms show a strongly developed laminated capsule within which the naked nerve-fibre finds its termination. Here, again, the element of insulation is clearly recognisable and the loss of the neurilemma is compensated for by a thick capsular structure. It has been generally supposed that these various terminal bodies owe their peculiarities of structure to the function they fulfil of transforming the physical stimuli they receive into the nervous impulses which give rise to the corresponding sensations. However this may be, it is difficult to avoid regarding the common feature they all show as evidence that the sensitive terminal nerve-fibrils are in very special need of absolute insulation from the other tissues.

The third type of structure that is found is the terminal arborisation. Here the fibril breaks up, loses its neurilemma, and in its uninsulated condition ramifies among the cells of the epidermis. When we see that everywhere else, without exception, the nerve-fibre throughout its course, up to and including its termination, is provided with an absolutely unbroken insulation, we cannot fail to regard the free arborisation as a remarkable anomaly. Now we know that these free nerve-endings are those of the fibres concerned with pain sensations, for they are the only ones that occur in the cornea, where the only form of sensibility is that for pain. Pain, then, is peculiar among sensations in being originated in and transmitted by a nerve-fibre of which the terminal ramification is uninsulated.

Up to this point we have reviewed a certain amount of evidence pointing to the possibility that the peculiarities of sensibility found in areas supplied by regenerating nerves are consequences of the abnormal conditions that necessarily accompany section and suture of a nerve. We have seen that where this operation is done conditions are set up which are minutely and elaborately guarded against throughout the nervous system. We have seen that these conditions are capable of producing disturbances of nervous function, and that the only state at all resembling them allowed in the normal is that of the end-organs of the pain nerves.

CHARACTERS OF PAIN SENSIBILITY.

This remarkable coincidence naturally tempts one to make some closer inquiry into the mechanisms of pain. Pain has long been recognised as peculiar amongst sensations in having no specific stimulus. All other sensations are excitable by one stimulus which can be expressed as a simple physical process. Touch is excited by a moving contact, heat by transference of heat to the body, cold by abstraction of heat from the body. Pain, on the other hand, is excited by a whole series of stimuli which cannot be generalised under any single character except perhaps the rather fantastic one that they might be harmful if they were stronger. The anomalous nature of the pain nerve is well shown in its ready excitability by the harmless faradic current and its complete indifference to the harmful X ray.

In comparison with the stimuli which excite the other forms of skin sensibility, those which are effective for the pain nerves are relatively gross and energetic. Again, the quality of the sensation pain is quite different from any other sensation in possessing a certain explosive suddenness and in impelling to some kind of motor response. In respect to its high threshold, its intensity, and its tendency to produce motor responses the pain of normal sensibility bears in its subdued degree a decided resemblance to the general characters of sensibility in the recovering area. It seems natural to suspect, therefore, that if the latter form of sensibility owes its peculiarities to an undue exposure of the recovering axis-cylinders to somatic contact, the normal pain fibre owes its anomalous characters, in comparison with other sensory fibres, to its terminal arborisations being exposed in a certain degree to a similar influence.

According to this view the essential fact in the physiology of pain is that the sensation is set up in fibres which are maintained in a special and peculiar condition, the consequence of which is that while they are not particularly sensitive to excitation, when they are adequately excited they yield an excessive response.

---

[1] The mysterious delay and even arrest in the evolution of a glioma that sometimes follows the making of a simple decompressive opening in the bone and dura over it is, perhaps, worth remembering in this connexion.

EVOLUTIONARY CONSIDERATIONS.

The result of this discussion has been to bring out the fact that in the peripheral sensory nerves there are two sharply differentiated classes of fibres; first, the pain fibres relatively insensitive to fine stimuli, but, as it were, "set" to yield energetic explosive responses; and, secondly, the fibres for tactile and thermal sensation sensitive to the finest stimuli and, as it were, muted down to yield only sensations of a mild and non-explosive quality in regard to which unperturbed discrimination becomes possible. What we may ask is the relation to one another of these two classes.

Between the lower invertebrate with a diffuse plexus-like nervous system scattered amongst the tissues, and the higher vertebrate with a definitely marked-off central nervous system, it is very obvious that a great change in the direction of centralisation has occurred. At the same time a change much less conspicuous but equally great has probably occurred in the direction of insulation and the complete differentiation and isolation of neural and non-neural tissues. Such a change, if our general argument is valid, would be necessary to effect the general damping down of sensation and the reduction of its urgency which alone would render possible the discriminative and deliberative delay of response that is characteristic of the higher animal. We need not suppose that any form of cutaneous sensation experienced by us is unrepresented in the invertebrate, but there seems to be some ground for suspecting that in the latter all forms of sensation normally have some of the urgency that survives in us only in the case of pain. According to this view it is the damping down of a large proportion of sensory fibres by complete insulation that has given us the finer kinds of cutaneous sensibility and enabled us to make deliberate rather than impulsive reactions to the majority of our contacts with the outer world.

As I have already suggested it seems difficult to suppose that in the evolution of cutaneous sensibility a stage has been passed through in which the animal was insensitive to so important a stimulus as light touch. The evidence is rather in favour of sensitiveness to moving contacts being as elementary and as primitive as any other sensory endowment of animal organisms. As long, however, as such stimuli give rise to sensations urgent in quality and impelling to immediate motor response, their value in bringing the animal into relation with its environment must be limited. It is the qualitative change which restricts these characters to sensations set up in the pain mechanism that allows the discriminative forms of sensibility to acquire their full value.

This discussion is not intended to embody a full and consistent theory of cutaneous sensibility. It is concerned with three apparently isolated groups of facts: (1) The peculiarities of sensibility in skin supplied by regenerating nerves as determined by experiment in the human subject; (2) the physiology of the pain mechanism; and (3) a certain group of facts in the structure and pathology of the nervous system bearing on its relation to the other tissues of the body. The purpose of the discussion has been to bring into correlation these three groups of observations and to show, however tentatively, that they can all be regarded as illustrating a principle fundamental to the very essence of a nervous system.

Bibliographical Note.

The work of Head and Rivers was published in *Brain.* The first of their series of papers appeared in 1905. All are to be found in Head's "Studies in Neurology," London, 1920, two vols. The observations of Morriston Davies and the author of this lecture are embodied in Experimental Studies in the Innervation of the Skin, *Journal of Physiology*, 1909, and the Peculiarities of Sensibility found in Cutaneous Areas Supplied by Regenerating Nerves, *Journal für Psychologie und Neurologie*, 1913. An elaborate paper based on an experimental nerve section in the human subject was published by Boring in 1916, Cutaneous Sensation after Nerve-division, *Quarterly Journal of Experimental Physiology*, vol. x., No. 1.

SPINAL ANALGESIA.

By B. HOLROYD SLATER, M.B. CAMB.,
F.R.C.S. ENG.,
MEDICAL SUPERINTENDENT AND SENIOR SURGEON, BRADFORD
MUNICIPAL GENERAL (ST. LUKE'S) HOSPITAL.

DURING the period May 1st, 1922, to Dec. 10th, 1923, I have done 400 operations under spinal analgesia on patients ranging in age from 10 to 78 years with no death that can fairly be ascribed to the stovaine employed. Two cases, it is true, died on the table, but both were in a moribund condition from perforated gastric ulcer of 36 hours' duration, and from acute gastro-duodenal ileus respectively. Another case should in fairness be mentioned. It is that of a man of 72, who died three days after radical cure of a large strangulated inguinal hernia, the cause of death being "pulmonary œdema." There was marked bronchitis before the operation. As the result of analgesia his systolic blood pressure dropped from 138 to 68 mm. He was practically unconscious during the whole operation, being apparently in a deep sleep, but he woke up and seemed perfectly normal before leaving the theatre. There was no change of colour, and respiration was slow and snoring, as might occur during sleep. The dose of stovaine was 0·05 g.

I make use of spinal analgesia in every available case, that is to say, in all operations below the diaphragm, when the patient consents and is not too young to be controlled, except in trivial operations not expected to last more than 5–10 minutes. A detailed list would take up too much space. Suffice it, therefore, to say, as showing the scope of the method, that it includes gastro-jejunostomy with appendicectomy (33 cases), cholecystotomy (14), perforated gastric or duodenal ulcer (9), appendicectomy (37 acute, 34 chronic), colotomy (15), hysterectomy (13), ectopic gestation (8), radical cure of hernia (36), strangulated hernia (14), amputation through thigh for senile and diabetic gangrene (13).

It must be admitted that 400 is a small number from which to draw statistical conclusions; nevertheless, the following comparisons may be of interest.

Of *operations that have been done under both spinal and general* (excluding, of course, all operations above the diaphragm and all below it that have not actually been done in this series by both methods), there have been :—

Under spinal (my own cases)—
400 with 22 deaths; death-rate 5·5 per cent.
Under general (surgical staff, including myself)—
1737 with 113 deaths; death-rate 6·5 per cent.

Excluding from the above figures all operations where the death-rate was nil under both methods—e.g., radical cures and inguinal and femoral hernia, curettage, piles, &c.—there remain :—

Under spinal—
241 with 22 deaths; death-rate 9·1 per cent.
Under general—
1116 with 113 deaths; death-rate 10·1 per cent.

By either standard the figures for spinal are 1 per cent. more favourable than for general.

Advantages of Spinal Analgesia.

Let me sum up what I consider to be the advantages of spinal analgesia

1. It is safer than "general." It can be used where ether is contra-indicated—e.g., in subjects of chronic bronchitis, arterio-sclerosis, chronic nephritis, acidosis, diabetes. Some of my cases are striking illustrations of this.

2. There are no chest complications. In this connexion it will readily be granted by all surgeons of experience that the fatal cases of ether bronchitis and pneumonia by no means represent all the anxieties and troubles arising through pulmonary irritation by ether in the elderly and fat type of patient. The surgeon who has never had the mortification of seeing his laparotomy wounds burst open, or their healing delayed from the strain of incessant coughing, aided perhaps by post-anæsthetic vomiting, has been lucky beyond belief. I repeat, there are no chest complications after "spinal."

3. The comfort of the patient is vastly increased. For the spinal patient there is none of the horror of "going under" or "coming out"; no struggling, no suffocation, no nausea, no vomiting, no outrageous thirst, no vile smell and clinging taste of ether. There is no post-anæsthetic headache with the technique employed. The patient can talk cheerfully to his friends immediately after the operation. There is no need for a special nurse, as after a general anæsthetic, to watch him, sometimes for hours, until he comes round. Except in gastric cases, fluids can be given by mouth immediately after, indeed, during the operation, which is much more comforting than fluid per rectum. An important point is that Fowler's position is possible immediately the patient returns to his bed, a saving of most valuable hours in acute abdomens with pelvic drainage, where every minute counts. Convincing proof of the advantage of "spinal" over "general" from the patient's standpoint is afforded by strolling successively through two wards that are in the throes of a "spinal" and "general" field-day respectively. One suggests a convalescent home, the other the deck of a cross-Channel packet in dirty weather.

4. There are practically no anæsthetic anxieties, no gagging, tongue pulling and piercing, no alternations of light with almost lethal anæsthesia.

5. Complete muscular relaxation can be counted on during the whole operation, affording excellent access to, and easy exit from, the abdomen. In laparotomies for intestinal obstruction, for example, there is no avalanche of bowels, and no trouble in closing the peritoneum. In rectal operations the sphincters are completely relaxed and need no stretching.

6. The duration of the operation is not of such vital importance, since the dose of analgesic is given once for all, and is easily sufficient for an hour.

7. There is no shock from the operation, the posterior nerve roots being virtually severed temporarily as regards the transmission of stimuli.

8. No special anæsthetist is required; an advantage in hospitals, especially at night, to the resident who would otherwise be called upon to anæsthetise an urgent case, a class of case which, above all others, demands but seldom gets the most skilled anæsthesia available.

9. The patient can be consulted during the operation when necessary, and I can recall cases where this has saved the necessity for a second operation.

10. The air of the theatre is the purer for the absence of ether and chloroform fumes, which makes "field-days" less tiring to all concerned.

Disadvantages of Spinal Analgesia.

As regards disadvantages, I know of none, provided the technique be correct, save the slight extra work which devolves on the surgeon. Only one of my cases, a member of our nursing staff, complained of headache after operation. In her case this was of a mild neuralgic character in the occipital region and radiating over the posterior surface of the neck on the right side. It did not begin until three days had elapsed since the operation (appendicectomy) and was easily controlled and cured by aspirin. Recently a man aged 70, after a radical cure of bilateral inguinal hernia (that on the left being strangulated), developed within two days what at first was taken for a large burn over the front of the left tibia; I now think this is a trophic ulcer due to injury to the cauda equina. It is healing rapidly. These two were the only cases in the whole series with sequelæ requiring treatment. Catheterisation after operations for piles and hernia is required far less frequently after "spinal" than after "general."

In three cases there was complete failure of analgesia and ether anæsthesia was required:—

1. Gastro-jejunostomy, where a badly fitting needle allowed the stovaine to escape.

2. Gastro-jejunostomy, where a full dose of stovaine was delivered intrathecally. The failure was probably due to intrathecal adhesions, as the patient was syphilitic and had had previous intrathecal treatment with N.A.B.

3. Appendicectomy. Here there was a poor flow of C.S.F., and the stovaine was probably delivered extrathecally.

In another case of gastro-jejunostomy, although analgesia was perfect, the woman was so worried about the apparent loss of her "poor legs" that ether was given to control her. (These four cases are not included in the series of 400.)

There were 13 cases in which analgesia was not perfect:—

Eight of these occurred early in the series, when, in the light of further experience, an insufficient dose of stovaine was used.

Two cases (both gastro-jejunostomy), after full doses of stovaine, required a small amount of ether. They occurred consecutively the same afternoon. The ampoules used were the first of a new box and were probably faulty.

Three cases were uncomfortable towards the end of the operation, but no general anæsthetic was given. The operations were respectively: gastro-jejunostomy (0·07 g. stovaine), for complete transverse rupture of the jejunum at its junction with the duodenum (0·07 g.), and appendicectomy (0·04 g.). In each case the dose of stovaine was too small.

Technique.

Morphia, gr. $\frac{1}{4}$ (gr. 1/12 for 10 years old), 20 minutes before the lumbar puncture, is the routine in all cases. Ordinary lumbar puncture needles, not specially fine ones, are used in all cases except the very fat, for whom I have had a special set made two inches longer than normal. The needle should be sharp, and its stylet should be an accurate bevelled fit at the point. The needle seating of the 5 c.cm. record syringe must accurately fit the needle. Both needles and syringe are sterilised by boiling in distilled water, and before being charged with stovaine all fluid should be expelled from them. The analgesic employed is stovaine with glucose (Barker's), ampoules of which, containing 0·1 g. of each in 2 c.cm., are supplied by Messrs. Allen and Hanburys. This is the maximum dose such as would be necessary in gastric and liver operations. Three-quarters of this is ample for hysterectomies and for the lower abdomen generally (unless the upper reaches of the abdomen are to be examined at the same time), and one-half suffices for operations up to the groin.

Whilst the needles are being tested and the syringe charged the patient is placed on the left side with the knees and chin held as close together as possible by the nurse. The flat of the back should be vertical. The anæsthetic couch should be capable of being raised at its middle so as to elevate the pelvis. Failing this, flat sandbags should be available for the same purpose.

I always make the lumbar puncture in the middle line, never to the side, usually between the second and third lumbar spines, sometimes between the first and second. The dense interspinous ligaments then act by their resistance, tightly embracing the needle, as a most efficient guide. Puncture of the dura can be heard as well as felt, when at once the progress of the needle is checked. It is never necessary to make more than one puncture through the skin. This is important, since this is the only painful part of the procedure. If for any reason the needle has to be withdrawn and reinserted, the same puncture can always be used by stretching or moving the skin over the spines. I never withdraw any C.S.F., and am of opinion that the cases of "spinal" cephalagia reported from Paris are due to the routine withdrawal of from 20 to 30 c.cm., and, to a lesser extent, the use of stovaine-billon, which depends for its effect on its diffusion through the subarachnoid space, a process difficult to control or limit. As soon as the flow of C.S.F. begins the dose of stovaine is slowly injected, collodion applied to the puncture, and the patient rapidly turned over on to his back. The head is strongly flexed and the pelvis raised to a height varying with the height of analgesia required. Being of higher specific gravity than the C.S.F., the stovaine-glucose runs up the cord to the desired level. Five minutes suffices for analgesia up to, and slightly beyond, the costal margin; three minutes is enough for operations below the groin. The head must be kept flexed during the transfer to the operating table, during the whole operation, and during the journey back to the ward. This prevents any danger of paralysis of the medullary centres and of post-operative headache. A screen is arranged to shut off the patient's view. It is important that there should be no unnecessary noise. Adrenalin, camphor, and pituitrin should be in readiness, though they are rarely required.

It is important to remember that the Trendelenburg position cannot be employed with safety. It is, however, found to be unnecessary even in hysterectomies, as the bowels pack away easily under the relaxed abdominal walls. The patient sometimes complains of faintness, for which, except in gastric cases, a little brandy or aromatic spirit of ammonia can be given. Slight and transient nausea or vomiting may occur (due, I believe, to an insufficient interval between the morphia and the lumbar puncture), but is never embarrassing. It is usual to give drinks of water or soda-water during the operation. There is always a fall in the systolic blood pressure, usually not more than 15–20 mm. In some cases, however, it is greater, and may cause slow pulse and pallor. In cases where this may be expected, and in patients whose initial blood pressure is low—e.g., after severe hæmorrhage—1 c.cm. of pituitrin is given after the lumbar puncture. In any case of the sort 10 minims of adrenalin (1–1000) intravenously is very effective. Pituitrin should not be given in gastro-jejunostomies. In one of my cases it caused such contraction of the gastric musculature as to make the operation most difficult.

In three cases of high analgesia the patient complained during the operation of aching, cramp-like pain under the scapula. It required no treatment, and did not interfere with the smoothness of the operation. The usual and normal experience is one of deep peace and tranquillity both for patient and surgeon.

STUDIES IN THE MALE BREAST.

BY HAMILTON BAILEY, F.R.C.S. ENG.,
SURGICAL FIRST ASSISTANT, LONDON HOSPITAL.

THE mammary tissue of the male is the leading, if not the only example of an external secretory mechanism which persists without actual or potential function. Fig. 1 shows a typical section of male breast. Ten specimens of the normal male breast from post-mortem subjects at the London Hospital between the ages of 6 months and 65 years were submitted to histological examination. In all glandular tissue was present.

Congenital Abnormalities.

(1) *Absence.*—Complete absence is exceedingly rare. Sir Jonathan Hutchinson described a case in a boy aged 3½.

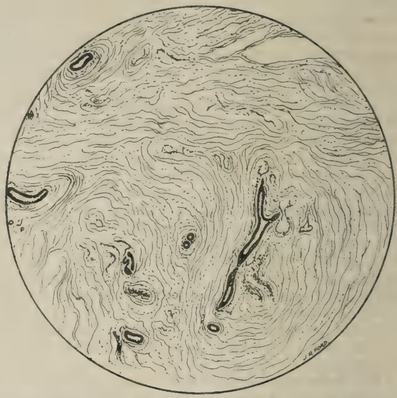
(2) *Supernumerary Nipples.*—Sir Arthur Keith has shown that accessory nipples occur upon a line extending from the anterior axillary fold to the groin. In certain communities these accessory nipples are relatively common; they were observed in 19 per cent. of 100,000 German recruits. In 100 consecutive male out-patients I was able to find them in only 2 per cent. They are liable to be mistaken for warts.

Hypertrophy.

(1) *Unilateral Idiopathic Hypertrophy.*—There are about 150 cases of this pathological curiosity on record. At puberty one breast enlarges and presents the characteristics of a well-developed female breast. Two cases of this kind have been operated upon at the London Hospital within the last 20 years.

(2) *Bilateral Idiopathic Hypertrophy.*—Gruber, of St. Petersburg, in 1866 collected 54 cases of male mammary hypertrophy. The breasts usually commence to enlarge at puberty, less frequently the hypertrophy is seen in childhood. Helen Ingleby described two cases in male children aged 7 and 8 respectively. Hyperplasia of the male breast is probably due to relative inadequacy of the internal secretion of the interstitial cells of the testes. Nevertheless, the subjects of this deformity are often virile—Chingawayo, the chief of the Zulus, a gynækomast, at the age of 55 had 40 wives and over 100 children. Although pseudolactation is most exceptional, cases have undoubtedly occurred. Schnetzer gives an account of a man whose breasts secreted 64 g. of fluid in 24 hours. Other German observers have noted similar though less striking instances. The secretion is not true milk, but has the appearance and chemical composition of colostrum. There is no evidence to show that the male has ever secreted true milk. Tribal tales of the father nurturing his motherless infant with milk from his own breast belong to the realms of surgical mythology. The ducts and acini are there, but the hormonic stimulus to activate them is always lacking. When the physiologist has isolated and compiled synthetically the specific hormone to stimulate artificially the mammary gland to physiological activity, the day may come when the male wet-nurse and the lactating bullock are commercial possibilities. The treatment of idiopathic hypertrophy is excision of the breast, for the deformity is liable to react upon the mental outlook of the patient.

FIG 1.



Drawing of microscopic appearance of typical section of male breast.

(3) *Hypertrophy Associated with Anorchism.*—It is well known that the male tends to assume female characteristics after castration in early youth. I am indebted to Prof. Turnbull for the following example of gynækomasty and gigantism in association with anorchism :—

A married man, aged 55, was admitted for heart disease to the London Hospital on April 19th and died on May 7th, 1910. At necropsy he was found to have subacute bacteriæmic endocarditis, a fibrosis of the liver of the "hob-nail" type, slight fatty infiltration of the pancreas, and a few small fat necroses in that gland. The corpse measured 6 ft. 3 in. in length, and weighed 15 st. 9 lb. A femur was excised and was found to be very large and heavy, but of normal texture. The breasts were large and prominent, but no secretion could be expressed from them ; the ducts and ductules on microscopic examination were found to be six times as wide as in control specimens from men of various ages ; the ducts contained a few desquamated epithelial cells, and some of the ductules a hyaline coagulum. The penis resembled that of a boy of eight or nine years of age. There were a few hairs on the mons Jovis, and a trace of down upon the upper lip ; the limbs and remainder of the trunk appeared hairless. The prostate was puerile. A firm cord passed on either side from small seminal vesicles to be attached to the base of the scrotum ; microscopic sections of the scrotal extremities revealed a solid cord of involuntary muscle, surrounded by adipose tissue which contained spermatic vessels and a few small bundles of smooth muscle ; there was no trace of testis or epididymis. The pituitary body was enlarged, measuring 1·4 by 1·7 by 0·8 cm.; eosinophil cells were massed in the central and posterior two-thirds of the anterior lobe, there were many conspicuous groups of large cyanophil cells in the remainder, and the tubules in the pars intermedia were distended with colloid. The thymus was replaced by fat. The thyroid gland, the pineal gland, and the supra-renal bodies were of ordinary appearance. No operative scars could be detected.

(4) *Hypertrophy following Malignant Teratoma of Testis.*—The male breasts may enlarge under the influence of abnormal gonadal internal secretion. This is illustrated by the following case:—

Motor mechanic, aged 32, admitted into London Hospital under Sir Hugh Rigby. March, 1923, orchidectomy for malignant left testis. Histological report: Malignant teratoma. May, complained of right breast getting larger. No pain. July, massive secondary deposits in lumbar glands became manifest. The breasts steadily increased in size. October, died. A necropsy showed simple hypertrophy of the breasts.

Parenchymatous Mastitis.

(1) *Mastitis of Infants.*—Is at least as common in the male as in the female. Its ætiology is closely related to the lactation of infants. On the third or fourth day of life, if the mamma of the infants be lightly pressed, a drop of colourless fluid can be expressed; a few days later there is often a slight milky secretion, which finally disappears in the third week. This is the "witch's milk," which observers have analysed and found to contain the essential characteristics of colostrum. The most ingenious (but not altogether satisfactory) explanation of this phenomenon is that the hormone which stimulates the mamma of the mother to physiological activity reacts also upon the newly-formed mammary tissue of the fœtus. In support of this theory it has been observed that in those infants whose breasts secrete plentifully the mother tends to produce large quantities of milk. The infant, with its breasts in physiological activity, is liable to the same danger of a retrograde bacterial infection as its mother. The cause of mastitis of infants is not the ignorant maternity nurse "breaking the nipple strings," for it occurs in babies born in hospital. Furthermore, the misguided midwife presumably limits her activities to the female infant's breast; and all who deal with the new-born appear to be agreed that mastitis of infants is, if anything, commoner in the male. Thus the midwife is exonerated. "Mastitis of infants" is essentially a physiological activity. It may lead to a true mastitis by retrograde infection. This true mastitis usually resolves; occasionally it suppurates. The following is a typical case in point:—

A male, aged 19 days, breast-fed infant, was recently admitted to the London Hospital under the care of Mr. A. J. Walton. The mother had been discharged from a maternity hospital seven days before. The baby's breasts were then swollen and secreting milky fluid. Two days before admission the left breast became red and painful. On admission there was a purulent exudate from the nipple and an abscess occupied the left breast. The breast was incised.

It is highly probable that some cases of persistent retraction of the nipple in after-life in both sexes are due to infantile mastitis. Primary abscess of the male breast in adolescent and adult life is seldom seen. Tuberculous mastitis is rare and usually secondary.

(4) *Mastitis of Puberty.*—This condition is frequently encountered in surgical out-patients. The boy aged about 14 complains of pain and swelling in the breast. In 80 per cent. the condition is mainly or entirely unilateral. On examination the breast is enlarged, tender, and slightly indurated. The treatment is expectant. Irritation should be avoided, and to this end braces are better substituted by a belt. Suppuration never occurs. The symptoms usually disappear in 14 days or less, but the induration was still present five weeks later in one case which was followed.

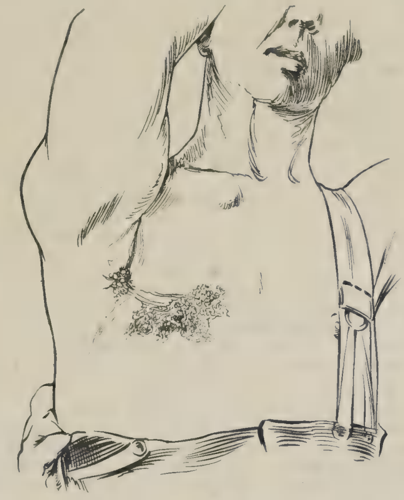
(5) *Mastitis from Local Irritation.*—This condition is another clinical entity. In civil life it usually occurs in manual labourers with ill-fitting braces. During the war soldiers carrying heavy equipment were seen with the same condition.

(6) *Mastitis as a Complication of Other Diseases.*—This is occasionally seen in mumps.

Interstitial Mastitis.

"*Chronic Interstitial Mastitis*" (diffuse fibro-adenomatous hyperplasia).—Of 11 males operated upon at the London Hospital for this condition six were over 55 years of age. It may thus be assumed that the condition occurs later in life than in the case of the female. All cases were originally unilateral. In two of them a similar condition, requiring removal, recurred in the opposite breast. Prof. Turnbull teaches that normally during the life of a woman the breast is in a condition of instability, undergoing evolution and involution not only during and after pregnancy and parturition, but at puberty, in the climacteric, and even, in many cases, at birth and during every menstruation; and that chronic interstitial mastitis is in reality an abnormal activity of similar nature. Inasmuch as chronic interstitial mastitis in the male presents precisely the same clinical features and histological appearances as in the female, it is necessary for the above explanation to show that the male breast also undergoes physiological changes. Under the headings "mastitis of infants" and "mastitis of puberty," it has already been shown that the male breast frequently enlarges at birth and at puberty, and these enlargements may be accompanied by the secretion of witch's milk. Further, a series of sections of the normal male breast at different ages showed an increase of the interstitial fibrous tissue as age advanced.

FIG. 2.



Carcinoma of breast of eight and a half years' standing. Patient cannot completely raise his arm because of cicatrisation around axillary glands (from a photograph).

Benign Neoplasms.—(1) Lipoma: Many of the lipomata classified in records of neoplasms of the London Hospital as occurring in the male breast appear to lie in the overlying superficial fascia. True interlobular lipomata are probably infrequent. (2) Fibro-adenomata: These are not exceedingly rare, and present the same clinical features as in the female. Cystadenoma of the male breast has been reported.

Malignant Neoplasms.—(1) Sarcoma: The records of the London Hospital contain two cases of sarcoma of the male breast, both beginning in the subcutis of the areola, and both occurring in men of middle age. (2) Carcinoma: Roger Williams, in collecting 2420 cases of carcinoma of breast, found that 1 per cent. of the total occurred in males. Of 14 males admitted to the London Hospital for carcinoma of the breast, more than one-third were totally inoperable.

From this fact the conclusion may be drawn that it is not modesty alone that deters the female from seeking relief for carcinoma of breast in the operable stages of the disease, but rather the absolute lack of symptoms. Of the nine men in this series on whom a radical excision of the breast was performed, the histological examinations showed seven spheroidal-celled and two columnar-celled. One of these cases, operated upon 11 years previously, recently returned complaining of hæmoptysis. Examination showed multiple recurrences in the sternum. Carcinoma of male breast runs an extremely atrophic course. Blair Bell described a case of two and a half years' duration. A case of eight and a half years' duration at present attending for X ray treatment at the London Hospital is worthy of notice :—

Carman, aged 44, in 1915 noticed breast was enlarged and bled when it was knocked. Two years later skin became ulcerated. He attended as an out-patient for the first time in August, 1923; his complaint was that he could not follow his occupation because of the inability to raise his arm above his head. He had 18 months before commenced to have difficulty in raising right arm, and 10 months later the left arm became similarly but less affected. Fig. 2 shows the extent of the ulceration and also the extensive cicatrisation of the axilla, which prevents him fully raising the arm. Further interrogation revealed that he had lost 1 st. during the past month, and had been troubled for 10 months with dry cough.

Paget's Disease. — The records of the London Hospital include one example of Paget's eczema of the nipple in a male. The patient was 43 years old. The breast was excised. The microscopic changes were typical of Paget's disease; there was no cancer.

Conclusions.

1. Congenital abnormalities of male breast are less frequent in this country than in Central Europe.
2. Infantile mastitis is not (as is commonly believed) traumatic in origin. It is a physiological activity which favours a retrograde bacterial infection, and thus may result in a true mastitis.
3. Persistent retraction of nipple in after life is sometimes due to previous infantile mastitis.
4. Evidence has been given showing that hypertrophy of the male breast is stimulated by the hormones which in the government of growth and development are antagonistic to the internal secretion of the testes.
5. "Chronic interstitial mastitis" in the male is, as in the female, essentially an aberrant evolutionary and involuntary activity. It occurs later in life in the male than the female.
6. Paget's "eczema" and every variety of new growth of the female breast have been met with in the male.
7. Cancer of the breast in man is usually atrophic in character, but the prognosis is poor, because, as a rule, relief is sought even later in the disease than in the case of the female.

My thanks are due to the surgeons of the London Hospital for permission to make use of their cases, and to the Director and Assistant Director of the Pathological Institute for their assistance.

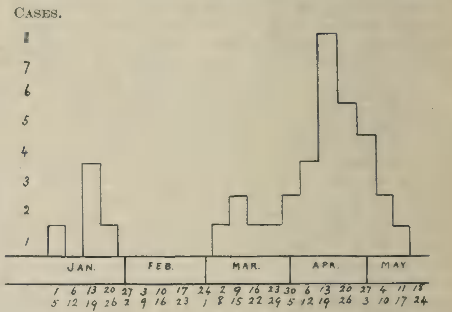
ENCEPHALITIS LETHARGICA WITH DIPLOPIA AS AN EARLY SIGN.

BY C. W. YOW, M.B., B.CH. EDIN.,
SENIOR HOUSE SURGEON AND SURGICAL REGISTRAR, THE ROYAL EYE HOSPITAL, ST. GEORGE'S CIRCUS, S.E.

ABOUT April, 1924, there was an enormous increase in the number of patients who attended here complaining of diplopia. This is shown graphically in the figure in which there is recorded by the author, working in conjunction with Dr. L. H. Savin, the number of cases presenting themselves with diplopia every week of this year.

This sudden increase was due to the epidemic of encephalitis lethargica, of which we have had 21 undoubted cases; while we have also seen 19 cases of diplopia due to other causes. In nine of our cases there was a history of a previous febrile attack. Usually the patient "knew he had influenza, so did not trouble to call the doctor." But the diplopia soon made the patient realise there was something wrong. With this diplopia was usually associated headache. At first (12 in 21 cases) they could not sleep; but after a few days drowsiness, with difficulty in opening the eyes, asthenia, and lethargy set in. After a time in many cases the diplopia ceased and the symptoms improved, but this was not invariable. A summary of these symptoms is given in the table.



Illustrative Cases.

CASE 3.—M. G., female. Had "influenza" about March 11th, 1924; this left her weak. Other members of the house also had "flu" about this time. On April 13th she felt "seedy" and began to see two of everything; this lasted only for half an hour. On the following day she got worse and "double vision" came on again and this lasted for five days. At the time she had headaches and felt very weak and drowsy. No overcrowding or gastro-intestinal disturbance. Eyes: Pupils react to light and accommodation, lateral diplopia; paresis of external rectus. When seen on May 14th she still felt weak and drowsy but had no diplopia. Her doctor reports that she made an uninterrupted recovery.

CASE 6.—W. C., male, aged 47. No definite influenza, but had "severe cold" in chest. First had malaria in 1916 and ever since has had frequent relapses of rigors and fevers, the last attack being on April 25th. A good sleeper as a rule, but had two sleepless nights previous to April 29th, on the morning of which, whilst going to work, he saw "two buses" when there was only one. He had headaches, felt weak, and began to sleep for 12 hours at a time; and still felt sleepy in spite of the rest he had. Tendency to constipation but no gastro-intestinal disturbances. No genito-urinary disturbance. Family, food, and housing accommodation negative. Eyes: Left ptosis with vertical diplopia. Visual acuity not affected. During admission he ran an intermittent temperature, which rose to 101° F. He was somewhat lethargic and placid. Blood examination showed no malarial or other organisms. He has made an uneventful recovery.

CASE 17.—W. H. N., aged 41, was an energetic man. At the end of March he began to see double, while convalescent from an accident in which he fell off a ladder.

He had nearly recovered from the accident when double vision began. At first he could not sleep, but now he is very drowsy and weak, the "antithesis of his former self, as all this laziness is foreign to him." The double vision lasted two weeks. Diplopia is now only elicited with difficulty. No fever at time of examination. Knee-jerks and ankle-jerks brisk. Left extensor plantar reflex was found.

CASE 19.—J. E. P., male, aged 29. On April 17th he felt "out of sorts with no appetite and lack of sleep." On the same day a severe headache began, and he had pains above the navel and in one elbow. Two days after he began to see "double" and was admitted into hospital. The temperature was 100·2° F. He had bilateral ptosis, vacant expression, and paresis of left external rectus. His right grip was weak. On the following morning he seemed disorientated and wished to know why he had been kept in hospital eight days. On dressing himself he laced up his boots and found he had forgotten to put on his socks. Wassermann was negative both in blood and cerebro-spinal fluid; a cell count of latter gave 68 lymphocytes and four red blood cells per c.mm. Tendon and superficial reflexes normal. He was transferred to a general hospital. The right optic disc was congested.

CASE 20.—E. B., boy, 5 years and 7 months. "Usually a demon." Previous illnesses whooping-cough, measles, followed by congestion of lungs. On April 9th he went to bed as usual about 7 P.M. Next morning got up cross-eyed and kept opening and shutting alternate eyes, though he made no direct complaint of diplopia. He had a headache, seemed drowsy, and did not want to go to school, which was unusual. Next morning (11th) he went back to bed himself after breakfast and slept all day, except when roused for meals, and all that night. Though next day he was awake for a time in the morning, he dropped to sleep during his dinner and dosed the rest of the day. This continued till April 20th, and while the other children played he lay on the grass and slept. On the 22nd he was brought to this hospital and slept while waiting his turn for examination. His temperature was 99·6° F. Admitted to hospital he slept the whole time except when roused, when he seemed quite intelligent. Wassermann negative. He described no diplopia, but there was a definite paresis of the right external rectus and right side of the face. The right hand grip was equal to the left, and he stated he used either hand indiscriminately "when he smacked his small sister." There were no other physical signs. Transferred to a general hospital he is now well on the way to recovery.

CASE 21.—E. G., female, aged 23, usually a "lively girl"; began to see double five days after an attack of "influenza" which she treated herself. On April 12th a friend went with her for a walk and she seemed "mopy," and on the way home "her eye went into the corner and she saw double." Two days later she came to hospital with weakness of both external recti causing diplopia on looking downwards and into the distance. She had severe headache and at first could not sleep. She then became drowsy and weak, and her friend states that when he calls she is always moping about, with her head on her hands, and will sit quiet for hours.

We have not attempted to split our series into various groups as suggested by American authors. For instance, they lay stress on a "mask-like face" as a sign of one type of the disease. Certainly many cases have an expressionless appearance, but we do not lay much stress on this point. In the course of a walk down Blackfriars-road we met 226 people, of whom 57 might be fairly said to have "mask-like faces," and yet the proportion was pulled down by a number of children just out of school.

SUMMARY OF SYMPTOMS IN PATIENTS COMPLAINING OF DIPLOPIA

The average age of our cases works out at 37 years. The disease affects males and females as 4 to 3 in our series. Our patients were not confined to any one occupation, but included clerks, housewives, bricklayers, domestics, shop-people, &c. From what we were told we are convinced that overcrowding played no important part in causation of this disease.

Eye Symptoms and Signs.—In every one of our recorded cases there was a definite history of double vision. This usually was sudden in onset and formed the prominent and early symptom of which complaint was made. This diplopia was in a good many cases associated with headaches, and was of a transient nature, lasting about one to four weeks in the mild, and for longer periods in the more severe instances. In several cases the diplopia was intermittent. The external recti were affected in 60 per cent. of the cases. In these it was usually a paresis, but in two cases from previous years (Cases 8 and 11) we have to record permanent paralysis. The vertical muscles were affected to a lesser extent and were usually combined with ptosis. Many complained of inability to keep the eyes open. Definite ptosis was recorded in three cases and was transient. No true nystagmus was recorded except in one case. We did not note any gross change in the pupils. In some cases the pupil of one side was more sluggish in its reaction to light. Only in one case was the accommodation paralysed. No fundus changes were found except in one acute case (Case 19) where we thought the right optic disc showed congestion.

General Symptoms.—In two-thirds of our cases there was severe headache associated with or preceded by diplopia. There was often a slight rise in temperature, and we think from the history fever is always present in the early stages of the disease. Wakefulness was an early sign and frequently preceded the onset of lethargy, asthenia, and drowsiness, which were almost invariably present. Even the most somnolent patient could be temporarily roused to pay some attention. Constipation, though present in some cases, was not a prominent symptom. The genito-urinary system was unaffected.

Diagnosis.—We have based our diagnosis on the clear clinical picture of diplopia, headache, fever, and wakefulness, followed by drowsiness, asthenia, and lethargy. The cerebro-spinal fluid was examined in a few cases but nothing pathognomonic was found. The Wassermann reaction is of value where the question of a syphilitic infection arises; but syphilitics are not immune to encephalitis lethargica (Case 16). Until some specific test is found we can rely very little on the laboratory except for negative diagnosis.

Relation to Influenza.—Several patients gave a definite history of previous "influenza," usually two or three weeks before the onset of diplopia. In one case all the other members of the house had "influenza" at the time and yet she was the only one to develop encephalitis lethargica. If the disease were contagious we should expect several cases in the same house, and this so far has not occurred.

Relation to Food and Botulism.—The majority of our patients were well nourished. In none of our cases were we able to assign any particular type of food as a cause in the onset of the disease. There were no gastro-intestinal disturbances.

Treatment.—Those cases which came under our direct supervision we treated with urotropine, iodides, and salicylates. We had very encouraging results; and in the absence of any specific remedy we think these drugs ought to be used more extensively. As purgatives we recommend calomel followed by salines.

Conclusions.

The series shows the type of case likely to attend an eye hospital. In view of the 100 per cent. of diplopia in our series we would urge that encephalitis lethargica should be borne in mind by the practitioner in every case of "double vision" encountered. Several of our patients first consulted their doctors for diplopia, but the real nature of the disease was not suspected. The present epidemic shows many mild and ambulatory cases, which are easily overlooked unless a systematic inquiry is made into the history.

We are much indebted to Mr. A. D. Griffith, Mr. T. W. Letchworth, Mr. E. A. Dorrell, Mr. W. J. Lindsay, and Mr. H. W. Beedham for permission to examine and report the foregoing cases.

THE INTRAVENOUS INJECTION OF ANTITOXIN IN DIPHTHERIA.

BY DONALD MACINTYRE, *M.C.*, M.D. GLASG., D.P.H. LOND.,
MEDICAL SUPERINTENDENT, PLAISTOW HOSPITAL;
AND
D. W. MCKAY, M.B. TORONTO, D.P.H.,
SENIOR ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

IN an article[1] published in THE LANCET last spring, Dr. Poul Iversen, of Copenhagen, strongly advocated the intravenous route for the injection of antitoxin in diphtheria. This aroused considerable discussion, from which it appeared that the intravenous method had been tried by various authorities in this country, but the results were not regarded as sufficiently striking to warrant its employment except in very severe cases. Subcutaneous and intramuscular injections are the methods mainly employed in this country. The latter has now become the routine mode of administration in most fever hospitals, but in general practice the subcutaneous route is still most commonly used. As the three methods are being practised to varying extents it may be of interest to give an account of our experience at Plaistow Hospital, especially of the intravenous route.

Subcutaneous Injection.

This was the method generally used in the early days of antitoxin treatment, and it continued to be the routine method at Plaistow until the year 1913. Its advantages as regards safety, simplicity, and average results, are so well known as to require no comment. It has one disadvantage, however, the importance of which may not be so fully realised, and that is the slow rate of absorption of the antitoxin from the subcutaneous tissues. It was pointed out recently by Prof. Madsen[2] that the absorption of antitoxic serum follows laws which are quite different from those applicable to crystalloids such as morphine, &c., where the effect is obtained in a few minutes. Experiments have shown that nearly three days elapse before the maximum concentration of antitoxin is obtained in the blood after a subcutaneous injection, also the total quantity present is only one-third of that obtained immediately by an intravenous injection. It can be seen, therefore, that this constitutes a very important disadvantage, especially in a severe late case of diphtheria. Subcutaneous injection has ceased to be employed for routine work at Plaistow, and is now only used very occasionally in giving a desensitising dose to a patient who has had serum before.

Intramuscular Injection.

This method was first used at Plaistow in 1913, and the results proved so satisfactory that it soon completely displaced subcutaneous injections for routine work. Its advantages over that method are very definite, the most important being the much more rapid absorption of the antitoxin. Experiments have shown that this is about three times as rapid and that the difference is very noticeable in the first ten hours, which is often a critical period for the patient. The method is as safe as the subcutaneous, and the technique quite as simple. The site chosen for the injection is the outer region of the thigh. There is no danger of injuring any important structures in this area, and a dose of 12,000 units can be given quite easily. Also the injection itself is less painful in this region than in some other parts of the body. It is the method now used at Plaistow for all mild and moderate cases of diphtheria.

Intravenous Injection.

In 1903, after a very favourable report had been published by D. L. Cairns[3] on 20 cases of diphtheria treated by intravenous injection at Glasgow, Biernacki and Muir[4] tried the method at Plaistow on 45 selected grave cases. Their conclusions were very conservative, but, on the whole, suggested that the method had some value as against other modes of administration. The trial was continued during the next two years, when a further report was published by A. O. Bisson[5] on 200 cases. In the cases treated by Biernacki and Muir the injections were given by incision under a general anæsthetic, but this was afterwards discontinued, and in most of Bisson's cases direct puncture was employed without an anæsthetic. Bisson emphasised the severe reaction which occurred in some cases after the injections, but he did not express any opinion on the value of the treatment, and apparently the results were not regarded as very satisfactory, for the method was discontinued shortly afterwards.

In 1921 the writers started to give the intravenous route another trial, and the results have been so encouraging that it is now used regularly for all severe cases. During the past two years 125 cases received intravenous antitoxin, and the following details are given of the treatment and our results.

Type of Case.—The intravenous injections have been given only to toxic cases, mostly of the naso-pharyngeal type, with extensive membrane on the fauces, enlargement of the cervical glands, and discharge from the nose. These cases were selected on account of their severity from 1025 diphtheria cases which came under treatment during the past two years. Within the last six months we have used the method also in laryngeal cases and the results have been encouraging. Sixteen laryngeal cases are included in this series. All the cases were late in coming under treatment. Table I. shows the duration of the illness on admission according to the history given by the relatives.

TABLE I.—*Duration of Illness on Admission.*

Days.	Cases.	Days.	Cases.
Two	12	Five	22
Three	32	Six and over	15
Four	44	Total ..	125

Dosage.—In most cases only the first dose was given intravenously, and was followed by intramuscular injections. The intravenous dose varied from 6000 to 40,000 units, the average being 18,000 units. The largest amount given at a single injection was 24,000 units. Eleven cases had all the serum intravenously in one or two injections; the rest had the initial dose only intravenously followed by intramuscular injections. The total amount of serum given to all cases of the series varied from 12,000 to 100,000 units, the average being 48,000 units.

The following two cases are quoted from the series as typical examples of the type of case selected for intravenous injection, and also showing the amount of serum given.

CASE 1.—A female patient, aged 8 years, was admitted on June 5th, 1923, on what was stated to be the fifth day of illness. Her tonsils were greatly enlarged and covered with thick greyish membrane extending on to the soft palate and uvula and the back of the pharynx. Both sides of the neck were very swollen and there was profuse discharge from the nose. The odour of the breath was markedly diphtheritic. There was a heavy cloud of albumin in the urine. The temperature was 100·6° F.; the pulse 124 and of low tension. On admission the patient received 20,000 units of antitoxin intravenously, and this was followed by three intramuscular injections at intervals of 12 hours, the total amount given being 70,000 units. No reaction followed the intravenous injection. On June 6th the nasal discharge had ceased, the glandular swelling had subsided, and the membrane was beginning to break up. On June 24th palatal paralysis set in and the knee-jerks were absent. A fortnight later ciliary paralysis developed. There was no serum sickness. By August 7th the nasal voice had cleared up and the vision was normal, but the patient had a marked diphtheritic gait. She continued to make good progress, and was discharged on the ninety-eighth day of her illness.

CASE 2.—A male patient, aged 4½ years, was admitted at 3 P.M. on Feb. 15th, 1923, the fourth day of his illness. Both his tonsils were completely covered with typical false membrane which extended to the soft palate and uvula. The glands at the angles of the jaw were much enlarged, and there was discharge from the nose. The patient also had a croupy cough. The temperature was 101° and the pulse 128. The urine contained a trace of albumin. At 4 P.M. 24,000 units of antitoxin were injected intravenously. About 40 minutes later a reaction of moderate severity set in, lasting for about 20 minutes. The temperature rose to 104° and the patient had a rigor. The laryngeal symptoms were aggravated during this time, but subsided as the reaction passed off. Two intramuscular injections were given at 12-hour intervals, making a total dose of 50,000 units. On the 17th the nasal discharge had ceased, the laryngeal symptoms subsided, and the membrane was breaking up. On the 19th the patient vomited and the pulse was soft and irregular. By the 22nd, however, the circulatory condition had improved, and from this time the patient made an uneventful recovery. There was no serum sickness and no paralysis. He was discharged from hospital on the sixty-fourth day of his illness.

Technique.—The injections have been given by direct puncture, usually into the veins of the arm at the bend of the elbow. In two cases of the series the external jugular was used. In no case has a cutting operation been performed or a general anæsthetic given. The arm is surgically cleaned at the elbow and held by a nurse well extended over the side of the bed or cot. The nurse exerts manual compression by grasping the arm tightly at the middle of the humerus with one hand while the other hand controls the wrist. No other form of tourniquet has been found necessary. The injection is made with an ordinary antitoxin syringe, care being taken that the serum has been warmed to body temperature. The puncture wound is afterwards sealed with a collodion dressing. The whole procedure is quite simple and comparatively painless, and after some experience there is little difficulty in making the injection, even in children of 2 and 3 years. The ages of the cases in the present series are shown in Table II.

TABLE II.—*Intravenous Cases Classified According to Age.*

Years.	Cases.	Years.	Cases.
0–1	1	10–11	12
1–2	2	11–12	5
2–3	5	12–13	3
3–4	9	13–14	6

6–7	13	Over 20	2
7–8	8		
8–9	7		
9–10	4	Total ..	125

Reaction.—In the majority of our cases a definite reaction set in about 40 minutes after the injection. Its onset was usually sudden with chilliness, which soon developed into a rigor. Pyrexia was a marked feature; the temperature often rose to 104° or 105°, and in a few cases it reached 106°. The pulse was often small and rapid and the respirations quickened. In a few instances the patient was slightly cyanosed at the height of the rigor. Vomiting occurred on seven occasions, and in one case a profuse urticarial rash appeared during the reaction and remained for half and hour. No reaction occurred in 24 cases. The severity of the reaction did not appear to bear any relation to the amount of serum injected. A dose of 6000 units caused a more severe reaction in some cases than 20,000 units did in others. On the other hand, there seemed to be a distinct connexion between the sharpness of the reaction and the severity of the case. Very toxic cases often had no reaction at all, or it was only slight. This feature has been so pronounced in our cases that we have been led to regard a definite reaction as a favourable sign, indicating a good resistance on the part of the patient. Two brands of serum have been used lately, one concentrated, the other unconcentrated. They were obtained from different makers. No difference could be detected in the antitoxic value of these two serums, nor was there any marked difference in the severity of the reaction caused by them.

Although the reaction was severe in some cases the symptoms could not be described as very alarming. When a sharp rigor set in warmth was applied to the patient by means of extra blankets and hot-water bottles; sometimes a hypodermic injection of 5 minims of camphor was given and occasionally, if the patient's colour was poor, inhalations of oxygen were given for a few minutes. The symptoms usually passed off completely after about 20 minutes, and the patient fell into a peaceful sleep. Recently, however, one case has come under our care where death occurred six hours after the intravenous injection. This was a boy, aged 10 years, who was admitted at 11 P.M. on August 26th. He was in the third day of illness and suffering from a severe attack of diphtheria. 18,000 units of antitoxin were injected intravenously and 10,000 intramuscularly about half an hour after admission. Forty-five minutes later he developed a severe rigor; the temperature rose to 107° F., the colour and pulse were poor, and he vomited. After 20 minutes the rigor passed off and the patient went to sleep. Within half an hour, however, the breathing became very stertorous and he was found to be unconscious. The pupils were widely dilated, the pulse imperceptible at the wrist; cyanosis was marked and the temperature had risen to 108° F. After about 15 minutes the breathing became quieter and the colour and pulse improved, but the patient never regained consciousness. Paroxysms of dyspnœa, lasting about 15 minutes, recurred at frequent intervals, and gradually tonic spasms set in. The patient died in a convulsion six and a half hours after admission. At the autopsy the thymus gland was found much enlarged and the lymphoid tissue throughout the body greatly hypertrophied. The post-mortem findings pointed to a condition of status lymphaticus. There was no indication on admission that an intravenous injection in this case might be followed by any untoward results, and we could only ascribe the fatal issue to the status lymphaticus found post mortem.

In Table III. the reactions have been classified according to severity.

TABLE III.

No reaction	24 cases.
Mild reaction	22 ,,
Moderate reaction	52 ,,
Severe reaction	27 ,,
Total	125

In the cases classed under Mild Reaction, the symptoms were a rise in temperature, not exceeding 102°, and a slight increase in pulse-rate, but no rigor. Under Moderate Reaction were classed cases with a rise in temperature over 102° but not exceeding 104°, an increase in pulse-rate and a mild rigor lasting about ten minutes. Under Severe Reaction the symptoms were a rise in temperature of 104° and over, a small rapid pulse, a marked rigor lasting for 20 minutes, and vomiting in some cases.

Serum Sickness.—Of the 125 cases injected intravenously, 58, or 46·4 per cent., had serum sickness. The rash appeared at periods varying from 3 to 14 days, the average being nine days. Three of these had had serum previously, and in each of them a severe rash occurred three days after the injection. In comparing the serum sickness among these intravenous cases with that which occurred during the same period among 900 other patients who had intramuscular injections only, no appreciable difference was found either in the date of onset or the severity of the sickness.

Results.

Fatal cases: 15 deaths occurred among the 125 intravenous cases. This gives a fatality-rate of 12 per cent. As these cases were selected on account of their severity from a total of 1025 cases which have been under treatment during the past two years, this mortality figure is not regarded as unsatisfactory. The following case is quoted from the 15 deaths as a typical example of the fatal cases.

CASE 3.—A female patient, aged 6 years, was admitted on Sept. 24th, 1922, on what was stated to be the fourth day of illness. Both her tonsils were much swollen and were covered with thick greyish membrane which extended on to the uvula and a portion of the soft palate. Nasal discharge was profuse and both sides of the neck were much swollen. The patient looked very toxic. The temperature was 100°, the pulse 120 and of low tension; 18,000 units of antitoxin were injected intravenously on admission, and this was followed by four intramuscular injections. The total amount of serum given was 62,000 units. A mild reaction followed the intravenous injection, the temperature rising to 102°. On the day after admission the nasal discharge was blood-stained, and ecchymoses were present round the sites of antitoxin injection. The urine became very scanty and was loaded with albumin. Vomiting began two days later, and the pulse became almost imperceptible at the wrist. Death occurred on Sept. 28th, four days after admission and the eighth day of illness.

Among the 900 cases which had been treated by intramuscular injections during the same period there were 46 deaths, a fatality-rate of 5·17 per cent. This includes 20 cases which died from laryngeal involvement. The total fatality-rate among the 1025 cases, which includes the 125 intravenous cases, has been 5·95 per cent.

Paralysis.

Thirty-two of the 125 intravenous cases had diphtheritic paralysis. This gives an incidence-rate of 25·6 per cent. The paralysis was mild in 15 of these cases and severe in 17. Among the 900 cases treated intramuscularly 45 had paralysis, an incidence-rate of 5 per cent. In 30 of these the paralysis was of a mild type and severe in the remaining 15. Altogether there were 77 cases of paralysis among the total 1025 cases, giving an incidence-rate of 7·5 per cent. The higher paralysis-rate among the 125 intravenous cases can be accounted for by the severity of the disease in these cases.

Conclusions.

Our experience during the past two years has convinced us that the intravenous injection of antitoxin is of great value in severe cases of diphtheria. The toxic symptoms subside much more rapidly than after an intramuscular or subcutaneous injection. The onset of paralysis also appears to be diminished. We were impressed by the number of cases in the above series which escaped paralysis. On the other hand, we do not advocate giving antitoxin intravenously to mild and moderate cases, where intramuscular injections have proved sufficient. As the reaction which usually follows an intravenous injection is sometimes very severe it seems unnecessary to expose moderate cases to the discomfort and even risk of such a reaction. For this reason we have only used the intravenous route in severe cases where there has been a definite risk of the disease proving fatal. The injection itself is simple and comparatively painless and it can be performed in young children.

Corrigendum.—Prof. H. M. Turnbull writes that the final sentence in his pathological report to Dr. A. W. M. Ellis's paper on Hyperglycæmia in Acromegaly (THE LANCET, June 14th, p. 1203) should run: "It can be called 'a mixture of neuroblastoma and embryonic neuroma.'"

Medical Societies.

LONDON DERMATOLOGICAL SOCIETY.

OCCUPATIONAL DERMATOSES.

ON June 11th Prof. MORITZ OPPENHEIM, of Vienna, delivered the annual oration of the Society at the Hospital for Skin Diseases, Leicester-square, on Affections of the Skin caused by Occupation and Profession. There was a goodly attendance, and the distinguished professor was introduced by Dr. J. M. BUNCH, President.

Dr. Oppenheim commenced by naming many well-known workers in this division of skin disease in various countries, including Adamson, Lett, MacLeod, and Sequeira. He said it had been computed that between 20 and 30 per cent. of all skin cases belonged to the occupational category. In these, cauterisations of the skin due to employment came first in frequency, followed by eczematoid conditions, while at the bottom of the list were the impetigoes. Burns and cauterisations of the skin might be due to electricity, to X rays, to radium, to acids. It was necessary to distinguish between a natural delicacy or susceptibility of skin and the action of irritants on the skin. The normal predisposition of the skin to react to these agencies and show lesions might be either heightened or diminished, therefore there was a distinct pathological susceptibility, and this might be either congenital or acquired. Congenital predisposition, in certain respects, was met with in the case of the brunette and the blonde. Various types of body had also to be taken into consideration, for both body and skin, in fact the whole system, must come into review. In the case of such congenital skin diseases as seborrhœa, ichthyosis, and psoriasis there was seen to be a constitutional predisposition to respond to irritation.

The irritations which attacked the skin were of complicated nature. He had experimented with such an apparently simple substance as vaseline. Sometimes it caused hyperkeratosis, at other times impetigo, at still others hyper-pigmentation. When it produced hyperkeratosis there was in the vaseline an excess of paraffin, and when hyper-pigmentation resulted there was an excess of colloid bodies. He showed the slide of an artificially produced vaselinodermia on the face of a child on which vaseline had been applied. There were to be seen many hyperkeratotic papules. In another case in which vaseline had been applied there was a dermatitis, with swollen eyelids and impetigo, due to the colloidal constituent, and probably also aided by bacteria.

The stigmata of occupational dermatoses were mostly transitory. He showed pictures, mostly in colour, of the hands of a dyer, showing a yellow staining, of a carpenter whose hands were stained with sulphuric acid, of a tinker whose hands had numerous fissures and callosities following the use of the tools of his trade. A shoemaker showed extensive lichen spinulosus on the chest due to the use of pitch at his work, known as a lower degree of "pitch skin." A miller showed a dark tattooing on the wrist caused by the impact of hot pieces of steel from the chisel when it was being sharpened on a grindstone; this stigma endured for a much longer time than most. Chronic cauterisations, resulting often in ulcers, were very frequent; they were caused mostly by lime, sulphuric acid, chromic acid, arsenic, &c. The skin changes caused by the passage of a strong electric current were due to the impregnation by the current of minute dust and metal particles. The condition known as chronic Rontgen dermatitis sometimes led to cancer. Soot, dust, and some powders caused an inflammation of follicles by obstructing them. Also, there were sweat gland affections, comedosis, and abscesses due to infection with staphylococci, the latter occurring in sebaceous glands, too. Benign skin affections, such as papillomata, were caused by petroleum, Rontgen rays, aniline dyes, &c. An arsenic burn on the foot was surrounded by a halo of inflammation. A typical burn produced by explosion of benzine was also shown. The man was working with his shirt open at the chest when the explosion took place, and the chest was covered by the burn. A man burned in a munition factory by an explosion of gunpowder had sordes-like lesions on the lips and much tattooing on the face. A galvaniser had acute nitric acid cauterisation on the back of the hand; there were yellow sores surrounded by irregular haloes, and in certain parts there were blisters. A tanner showed acute cauterisation ulcers on the wrist and chronic ulcers on the tips of the fingers. Other ulcerations shown were produced, respectively, by potassium, ammonia, and sulphuric acid; in some instances there were pre-ulceration blisters. Trench-foot of the second and third degrees was also depicted; there was a huge bullous affection of both feet, and a great degree of disfigurement. Amputation was necessary. Sulphuric and oxalic acid burns showed a black and deep ulceration, and it was necessary for such patients to remain from work for a long period. A skin change shown resulted from the passage of a current of 110 volts. Metal-dust impregnation, chiefly copper, produced a very enduring stigma; the tattooing was mostly in the deeper layers of tissue. The wire conveying current of very high power touched a man's body and produced a deep groove in the tissue beneath the shoulder, with radiating lines of cauterisation in the near neighbourhood. The man died from the shock. Radium burns produced a charring with crater-like ulcerations. The man had had radium applied for psoriasis vulgaris. A man with folliculitis of forearm conveyed it to his genitalia by contact. Pitch caused comedone formation and folliculitis, with acne scars and sycosis-like confluent lesions, with hyper-pigmentation. A paraffin worker developed a benign tumour in the scrotum, and an arsenic worker exhibited a cancer-like growth. Onychomycosis was found in bakers, and certain substances handled in the course of occupations caused a falling out of hair and a hyperkeratosis. Toxidermias, dermatitis circumscripta, and eczema resulted from a sensitive condition of the skin; there was a suitable medium for the entrance of chemical irritants; there might be an acute and generalised affection of blood-vessels. In eczema there was a change in the reaction. Photographers suffered from nail affections due to the use of silver lotion. Among the illustrations of toxidermia was one of the head of a gardener who had swollen eyelids, forehead, and nose following irritation of a boxwood tree, and the hand of a carpenter whose poison was the resin of satin-wood. One case had desquamation of the skin of the face following the use of jute; another had dermatitis circumscripta following work in a boot-polish factory, and a petroleum worker showed the same condition. A galvaniser exhibited desquamation, redness, and superficial sores in the folds of the skin. Healing took place after ceasing work for eight days, in which respect it was in striking contrast with eczema.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Section of Medicine was held on May 30th, Dr. T. G. MOORHEAD, the President, being in the chair.

Dr. L. ABRAHAMSON read a paper on three cases of

Epidemic Encephalitis with Painful Myoclonus.

The first case was that of a male, aged 11, who was admitted to hospital on March 13th last in an unconscious condition, with pupils sluggish and eyeballs oscillating slowly from side to side. Examination of the abdomen showed sharp spasms of the upper recti at a rate of about 60 per minute. The spasms were not completely rhythmical. Tendon reflexes and abdominal reflexes were absent. Lumbar puncture yielded a clear fluid with lymphocytosis. On the day of admission the patient developed an epileptiform attack; two days later slight strabismus was marked on the right side. On this day consciousness returned and complaint was made of abdominal pain. This subsided after two days and intense pruritus appeared which lasted for a fortnight. The abdominal spasms continued without remission. Pyrexia was slight and remittent. The patient was discharged from hospital on May 15th; spasms were still present in the recti and external oblique muscles.

The second patient, aged 19, was admitted to hospital on March 23rd complaining of severe abdominal pain. Examination of the abdomen showed the presence of sharp, but not completely rhythmical contractions of the muscles at the rate of about 70 per minute. The muscles involved were the recti and the right external oblique. The contractions were very forcible and were associated with intense pain. Temperature 99° F., pulse 102, respirations 26 per minute. The pain increased and the abdominal contractions were so forcible that the bedclothes were lifted with each spasm. Lumbar puncture yielded a clear fluid under increased pressure. Later the pain became agonising, the contractions spread to other groups of muscles and were so violent that they shook the bed. After some days the spasms and the pain subsided and delirium set in. The delirium was of the "occupational" type. The patient was noisy, restless, and at times difficult to control. Severe pruritus occurred and it was found necessary to bandage the hands. Transient ptosis was observed on April 2nd. Delirium gave way to unconsciousness and coma. The patient died 17 days after admission. A post-mortem was performed by Dr. E. C. Smith. The naked-eye appearances consisted of small hæmorrhages into the meninges. The vessels of both the brain and cord were injected and some of them were thrombosed. In sections, minute hæmorrhages were seen in the cortex, the pons, medulla, cerebellum, and cervical region of the cord. Perivascular infiltrations were found which consisted of lymphocytes with occasional plasma cells, arranged in a halo-like manner round the vessels. The changes were most marked in the region of the optic thalamus, pons, the island of Reil, and the cervical region of the cord. Hæmorrhages were found in the heart, spleen, kidney, and liver. Numerous groups of plasma cells were found in the spleen.

The third case was that of a male, aged 57, who was admitted to a nursing home on May 18th complaining of pain in the back of the neck and of insomnia which had lasted for three days. Examination showed spasms of the right upper rectus, right trapezius, and right erector spinæ muscle. These spasms occurred at a rate of 16–20 per minute and were irregular both in strength and in time. Spasms continued and spread to other groups of muscles. Pain was intense and insomnia complete until the 20th, when the patient slept for some hours. After this spasms and pain were absent for some days, but delirium of the occupational type set in. At times control was necessary. On the 25th spasms reappeared in various groups of muscles, delirium became continuous, and severe pruritus was noted. Ptosis of the right eyelid was noted. Some days later unconsciousness set in, the breathing became stertorous, the sphincters relaxed. Picking at the bed-clothes was continuous. On the 29th the patient died. The temperature chart showed a remittent form reaching 102·6° F. on the day of death.

Dr. Abrahamson stated that of 12 cases of encephalitis seen by him recently, seven had belonged to this type. He dealt with the question of nomenclature and suggested that "encephalitis multiformis" would be a more appropriate title than any of the names suggested hitherto.

Discussion.

Dr. R. J. **ROWLETTE** said that at Mercer's Hospital during the last couple of months there had been five cases of encephalitis, and the difference in symptomatology between these cases and cases of the disease which he had seen in 1918 and 1919 was striking. At that time lethargy had been the most striking feature about the cases, but now there was myoclonus, alternating with lethargy and delirium. The lethargy varied very much, as sometimes it was very slight and the patient could be roused, and at other times the patients went from a lethargic state into a state of coma, from which they could not be aroused. He had noticed that when the patients were aroused they were quite alert and could answer questions intelligently, but they only remained like that for a very short time, and soon became delirious again. The muscle most commonly affected with myoclonus was the rectus abdominis, and the left rectus abdominis was usually more affected than the right. It was, of course, noticeable in other muscles too. The type of encephalitis now seen was an active type, whereas in 1918 and 1919 it had been a more passive type. He thought that the difference in the symptomatology of the disease could be regarded as being due to the different parts of the central nervous system which were affected. It had to be remembered that one was dealing with an infection which might attack any part of the nervous system. It had been suggested that the disease was a manifestation of influenza, but he did not agree with this statement. There had been cases of encephalitis in other countries before the influenza epidemic occurred, but it was, of course, possible that these cases were forerunners of the epidemic. It had also been suggested that the disease might be due to Pfeiffer's bacillus. If this was the case, it was curious that this bacillus was not separated readily from the lesions in the central nervous system. He was of opinion that so far there was no established connexion between any bacillus and this disease.

Dr. J. **O'DONNELL** drew attention to three typical cases of the disease which had come under his notice. One was that of a girl, who at first was choreic in type, but gradually passed into a lethargic state, with loss of vision. The second case was a man who had been lethargic from the beginning, and had had visual disturbance, accompanied by myoclonus, and now greatly resembled a case of peripheral neuritis. The third case was a male student, who at the beginning complained of generalised pains and defective vision. Acute mania set in, followed by delirium, and the patient got violent and had to be removed to an asylum, where he died after three days.

Dr. W. C. **MACFETRIDGE** drew attention to the fact that while none of the cases reported by Dr. Abrahamson had complained of eye symptoms, all Dr. O'Donnell's patients had suffered from defective vision, and that while some of the patients were lethargic, others suffered from insomnia. He agreed with Dr. Abrahamson that the name lethargica should be given up, as it was a misleading one. It would be interesting to know how the patients got on after they left hospital. He understood that some of them afterwards developed Parkinson's disease. He had seen one case in which the principal symptom had been loss of vision, but this particular case had made a complete recovery. It was apparently a disease the severity of which varied greatly, and although there were some fatal cases, he thought that there were a great many mild cases which got completely well.

Dr. W. G. **HARVEY** said he had recently seen a case of a little boy who was of the choreic type, and had a perfectly regular clonus on the rectal muscles of the thighs. Although the boy complained greatly of abdominal pain, Dr. Harvey had not been able to satisfy himself that this pain was due to clonus of the recti muscles. There was no marked rigidity of the abdomen. There was insomnia at first, but the patient soon became lethargic. It was interesting to note the difference in type of cases of this disease—some went through an irritative stage at the beginning, and gradually passed into a lethargic state, but most cases he had seen seemed to be lethargic from the beginning.

Dr. A. R. **PARSONS** asked if optic neuritis was ever found in cases of encephalitis, as in all the cases he had seen the fundus had been perfectly normal. The cases he had seen had had abdominal pain, but no myoclonus. In one case he had seen catalepsy, and this patient, after being unconscious for several days, recovered. Any cases he had seen in 1918 had been Parkinsonian in type, but all his cases lately had been delirious.

Dr. H. **BEWLEY** asked what the prognosis in cases of encephalitis was. He had seen a case three years ago, and although the patient recovered, for a year afterwards she was melancholy and stupid. He had lost sight of her since, so did not know whether this condition still persisted. This year he had seen a student who had apparently had an attack of acute mania, and he also had distinct diplopia. After about a fortnight this disappeared and the patient left hospital and was sent home. That was three months ago, and he had recently seen the patient again and his mind was not right, as he could not concentrate properly upon anything. It would be interesting to see whether this condition persisted, or whether the patient's mind gradually got normal. Having regard to these two cases, he would not like to give a prognosis of real recovery in acute cases of encephalitis.

Dr. C. **PRESTON BALL** asked how many of Dr. Abrahamson's cases had got well while in hospital, and how they got on when they left. He had recently seen a case of typical Parkinson's disease, and the patient said that he had not long left hospital after recovering from encephalitis.

Presidential Summing-up.

The **PRESIDENT**, in summing up, said that the discussion that evening had mainly centred on the great variety of symptoms presented by the disease, and on the apparent change of type since the disease had first become prevalent. He himself had only seen three myoclonic cases, through the kindness of Dr. Abrahamson, but he had seen a fair number of cases of the choreic type, and many with lethargic symptoms.

Regarding the ultimate prognosis, he was inclined to think that, on the whole, children were more likely to make a complete recovery than adults. At any rate, he knew of some children who had suffered from the disease in 1919 and who had remained in every way normal since then, while in most adult cases nervous disorders of one sort or another usually supervened. Concerning treatment, he thought all were agreed that symptomatic methods were alone of any use. He had himself given up lumbar puncture, except as an aid to diagnosis. The relationship of encephalitis to influenza was still sub judice, and he knew of no well-confirmed evidence that influenzal vaccines had had the least effect on the course of the disease.

Dr. **ABRAHAMSON**, in replying, stated that of the 12 cases referred to by him, four had died. Treatment had been mainly symptomatic. Vaccine treatment was, in his opinion, empirical and useless. Four cases seen by him in consultation had been treated by a vaccine (antigen) of Pfeiffer's bacillus; of these two cases had succumbed. In one of his cases the patient developed hæmaturia, attributed by him to the use of large doses of hexamine. He referred to the occurrence of abortive cases. Lumbar puncture had not yielded much help. He agreed that the prognosis was better in children.

Dr. **PARSONS** read notes of a case of Universal Herpes, which were discussed by Dr. L. L. **CASSIDY** and Dr. N. M. **FALKINER**.

Dr. **HARVEY** read a note on 14 patients with Fur Dermatitis.

SCOTTISH SOCIETY OF ANÆSTHETISTS.

AT the annual meeting of this Society, held at the Royal College of Surgeons, Edinburgh, on May 17th, Dr. H. P. **FAIRLIE** (Glasgow) opened by reading his presidential address on the subject of

Anæsthesia: its Present Position.

Dr. Fairlie introduced his subject with a consideration of the position and status of the anæsthetist. He said that while in London the administration of anæsthetics had been more or less in the hands of the specialist since the discovery of the anæsthetic properties of ether and chloroform, such names as Clover and Snow being sufficient reminders of this fact, in Scotland the specialist was of more recent origin. Until about 20 or 30 years ago the Scottish surgeon depended, to a considerable extent, for the anæsthesia of his patient on the assistant, house surgeon, or general practitioner in charge of the particular patient on whom he was operating. But with the amazing developments which had taken place in surgery during those years the demands on the administrator of anæsthetics had grown, and now the anæsthetist in Scotland could regard with satisfaction the improvement which had gradually taken place in his lot. No doubt, he said, there was still room for improvement in several directions as, for example, in the information vouchsafed to the anæsthetist in the booking of appointments. It was hardly justice to patient, surgeon, or anæsthetist to have the bare fact of an appointment at a certain time and place communicated, as there was a considerable difference in the methods required for anæsthetising, say, a whitlow, a cholecystitis, a goitre, and a cleft palate.

In consideration of the anæsthetics at present available, the speaker confined his remarks to those which were in more general use, and to the newer methods of administering them. On the old controversy on the respective merits of ether and chloroform he did not intend to say much. His choice of anæsthetic, whether ether, chloroform, or other drug, depended on the exigencies of the particular case. In connexion with chloroform he touched on three points. He did not agree with Flagg, who said in his recent edition of "The Art of Anæsthesia":

> "In the author's experience, chloroform has completely given way to ether administered by intra-pharyngea methods. This condition holds with the single exception of oral cases in which the actual cautery is used."

If it was used, however, it should be done with very great circumspection, and, in the speaker's opinion, by some form of dosimetric apparatus which controlled the vapour strength. Further, chloroform should not be given at all in acute sepsis, particularly of the abdomen, because of the risk of acidosis, and finally it should not be used except by the expert. Adequate anæsthesia could be maintained, and anæsthetic mortality considerably reduced, by a more general employment of open ether in the hands of house surgeons and those who only occasionally gave anæsthetics.

With regard to ether, so many new methods and appliances had been introduced that it was almost impossible to keep up to date. The speaker considered the most valuable innovation in giving "open" ether was the perhalation method which Dr. A. Ogston described to the Society two years ago. A slight modification of it which he found most useful was to combine it with the bomb method of Wilson and Pinson, leading the tube from the bomb between the layers of gauze in Ogston's mask, and thus introducing warmed vapour instead of dropping liquid ether on to the gauze. In addition to the advantage which the warm vapour gave, there was also the freeing of the hand which was usually occupied with the drop-bottle. Shipway's apparatus for warmed chloroform and ether vapours he found invaluable in face, mouth, and nose operations, where a mask was inconvenient to the surgeon. Rectal anæsthesia, using Gwathmey's ether oil mixture, was of great service in laryngoscopic and bronchoscopic examinations. The intra-tracheal method, either with ether or chloroform, constituted, in his opinion, the greatest advance in the science of anæsthesia. The confidence which it inspired both in surgeon and anæsthetist in four classes of operations was of a nature that no other method achieved. These four classes were: (1) extensive face and intra-oral operations; (2) removal of goitres or other tumours about the neck; (3) lung surgery; (4) any operation entailing awkward positions for the patient.

Although gas and oxygen had been used for anæsthesia for over 50 years, its vogue had greatly increased lately. It had very definite limitations, but having strict regard to those it made an almost ideal anæsthetic in its own field. Administered after preliminary narcotics, with re-breathing, and with the minimum of ether or chloroform, it possessed very pronounced advantages in operations where a great degree of muscular relaxation was not demanded. Even in the latter class of case more use might well be made of it provided the surgeon was prepared to use novocaine locally in the tissues of the abdominal wall. Dr. Fairlie said that he did not restrict the use of oxygen to its accompaniment of nitrous oxide. His inclination was to use it more and more along with ether and especially chloroform. Any mixture of anæsthetic vapour and atmospheric air suffered from the high proportion of nitrogen. If the need for deep anæsthesia arose, this acted as a handicap—in other words, anæsthesia might be pushed further, with a greater degree of safety, in presence of a higher proportion of oxygen than the atmosphere contained. So in abdominal operations, particularly those of the upper abdomen, he frequently found a stream of oxygen led under the mask of great assistance. It prevented the onset of cyanosis with accompanying rigidity. It was useful in any operation where the patient, for one reason or another, had a tendency to cyanosis.

In conclusion, he pointed out that he had made no reference to spinal anæsthesia, from the feeling that it would introduce too large a subject.

In the discussion which followed, Dr. J. S. ROSS (Edinburgh) said that it was important that the administration of chloroform should not become a lost art, and that it should be adequately taught to students. With regard to rectal anæsthesia, he considered that if surgeons would inform the anæsthetist in advance of patients who were terror-struck, rectal anæsthesia might have a wider field of usefulness. He held that no theatre was properly equipped if it did not contain an oxygen cylinder with oxygen in it. The danger of nitrous oxide and oxygen lay in attempting to handle with it patients of too powerful a type, and in being ashamed to use adjuvants such as ether and possibly a little chloroform.—Dr. Ross Mackenzie (Aberdeen) agreed with previous speakers that students should be adequately instructed in the administration of chloroform. At the Sick Children's Hospital, Aberdeen, the majority of cases were conducted under nitrous oxide and oxygen combined, with very careful use of local infiltration with novocaine. With this help he considered that nitrous oxide and oxygen covered the largest field in children. An unusually high proportion of oxygen was required for a child and a mere trace of ether vapour during the induction period. There was very little after-sickness and a very rapid recovery. He had used rectal anæsthesia a good deal with children and personally liked the immediate results, but it threw a good deal on the nursing staff, and surgeons were inclined to think that there was more after-reaction than with the inhalation method.—Dr. A. Ogston (Aberdeen) thought the very best relaxation could be obtained with gas oxygen if, in addition to the local infiltration at the seat of operation, the intercostal nerves were blocked as they emerged from the lower spaces.—Dr. J. Johnson (Aberdeen) agreed as to the importance of adding oxygen to open ether; particularly was this of value when the induction was expedited by the preliminary use of open ethyl chloride which was apt to lead to a little cyanosis unless oxygen was added.—Dr. A. Mills (Dundee) did not agree as to the teaching of chloroform to students, considering it much more important to teach them open ether well and to impress on them the added dangers of chloroform. With regard to intratracheal anæsthesia he thought it was often unnecessary; if the surgeon were careful to mop out blood most of these cases could be met by pumping ether vapour with oxygen through the nose into the pharynx.—Dr. J. S. Frew (Glasgow) confirmed the value of oxygen with open ether or chloroform.—Dr. F. L. Napier (Glasgow) said he had come to rely very largely upon the Shipway apparatus for ether with a little chloroform added. He also was a great believer in adding oxygen to the combination, and used it to bubble through the apparatus instead of air.—Dr. W. Barras (Glasgow) agreed with Dr. Napier. He said that where malignant disease was present in the mouth he avoided the intra-tracheal method if possible, as he considered it quite a possibility that the catheter might carry infection down into the lung.—Dr. Torrance Thomson (Edinburgh) considered it certain that when out in the world young practitioners would use chloroform very freely, and he therefore thought it essential that in their student days they should be taught it. He used oxygen both with open and closed ether and had found Pinson's oxygen valve of great value. He was a warm advocate of the use of the intra-tracheal method for abdominal sections, particularly for a high operation such as gall-bladder. He had had good results with nitrous oxide and oxygen given by this route, but found it very expensive. He had had very good results with ethanesal, but upon the whole he doubted whether it was really any better than a good brand of ether. For some months he had been using the Pinson bomb and regarded it upon the whole as the best method for open ether.—Dr. Logan Turner (Edinburgh) expressed his appreciation of the invitation to him by the Society to attend the meeting and join in the discussion. He had always favoured the closest coöperation between various specialists, and certainly between the surgeon and the anæsthetist. He quite agreed that the anæsthetist should be informed precisely of the nature of the case and of all relevant points in connexion with it as soon as the appointment was made. In these days he had found very often that the anæsthetist's preparations required to be as complicated as, or more so, than those of the surgeon.

Dr. Fairlie, in reply, said that with regard to the teaching of the students, he personally favoured a deliberate attempt being made to wean the new members of the profession altogether from the habitual use of chloroform, and thought, therefore, that in teaching all the emphasis should be laid upon the simpler methods of giving ether.

Dr. J. H. Gibbs (Edinburgh) opened a discussion upon

Methods of Anæsthesia in Nasal, Dental, and Other Oral Operations.

He explained that he would simplify his remarks by speaking mainly of the methods which he personally used, and would exclude mostly from his observations the question of individual peculiarity in the patient, considering the anæsthetic solely in connexion with the locality or disease to be dealt with and not with any constitutional complaint such as cardiac or pulmonary disease. Mouth and nose operations had this peculiarity that the interests of the surgeon and the anæsthetist in many cases seemed to clash; each wanted to get at the patient at the same time. If ether was to be given he insisted upon a preliminary dose of atropine. One-hundredth of a grain was usually an adequate dose. If hæmorrhage was not likely he added heroin or morphia. Upon the whole, he thought that heroin gave less after-effects. His stock method for longer cases, such as antrum operations, was to induce with ethyl chloride and ether given with the Clover instrument and then change over to a Junker or Shipway, passing the vapour where possible along a catheter through the nose into the pharynx. For tonsils or adenoids in subjects up to 12 or 14 years of age he habitually used ethyl chloride, regarding 4 c.cm. as the maximum dose; latterly, he had been adding 1 c.cm. of ether and desired an expression of opinion from other members as to whether this addition increased the safety of ethyl chloride. For enucleation of tonsils, for which ethyl chloride alone would be inadequate, he used the Clover method of ether, getting a forecast from the surgeon as to the length of time which it would be desired the patient should remain under the anæsthesia. Here it was very necessary that the patient should have atropine, but morphia was undesirable. For paracentesis of the antrum nitrous oxide often sufficed. For mastoid operations he induced with ethyl chloride and ether in the Clover instrument, and followed up with open ether. For dental work he found that nitrous oxide or nitrous oxide and oxygen as a single-dose anæsthetic sufficed for anything up to three teeth, as a rule. For cases taking a little longer than this he added 1 c.cm. of ethyl chloride at the last moment. The patient need only take about five breaths of this, and some 10 seconds or more were thus added to the available anæsthesia. For cases demanding even longer time he used up to 2 or 3 c.cm. of ethyl chloride. Working on these lines, he had given 30,000 administrations of ethyl chloride or ethyl chloride and gas without fatality until recently, when he unfortunately had had a death in the dental department of the Royal Infirmary. The patient was sent to him for the extraction of 15 very septic teeth; she was absolutely panic-struck; he began the anæsthesia by giving her 3 c.cm. of ethyl chloride by the vapour method; during the early part of the administration she screamed almost continuously; she finally, however, went under, the colour remaining good. One tooth was extracted, when a slight amount of pallor and faintness of respiration was observed, the pupil remaining small, and he proceeded, therefore, to take out another tooth. The pallor then increased and he therefore stopped operating and had her lowered to the floor and commenced artificial respiration. The surgeon on duty was sent for and opened the abdomen in order to give cardiac massage, but by this time the patient was dead and did not respond in any way to the treatment. The patient was known to have suffered from rheumatic fever, but her heart had been thoroughly examined by a physician before the anæsthetic and was believed to be perfectly sound. Owing to difficulties with the relatives it was most unfortunately impossible to secure an autopsy. It was arguable that this death was mostly due to the delayed effects of fright, but since the occurrence he had resolved always to add 1 c.cm. of ether to any ethyl chloride which he gave. There could, of course, be no absolute proof that this added to the safety, seeing the infinitesimally small death-rate from ethyl chloride given in the doses that he advocated. He had used nasal gas and nasal gas and oxygen extensively, but found that the ordinary nasal inhaler interfered a good deal with the work of the dentist. He therefore preferred his own appliance, which he showed to the meeting, where the gas was led by tubes into each side of the nose, the anterior nares being plugged by his instrument around the entering tubes. In working with nasal methods he had found great advantages from the use of a large sponge pushed on to the dorsum of the tongue; even with single-dose methods he used this sponge, believing that it prolonged the anæsthesia without producing any serious embarrassment of respiration. Small sponges as used by some dentists were dangerous. He emphasised the danger of anything but a straight sitting-up position for extraction of teeth. He had an extensive experience of intra-tracheal anæsthesia, but even now he thought the best results were obtained in malignant diseases of the mouth by doing a preliminary tracheotomy and packing the upper orifice of the larynx.

Dr. **LOGAN TURNER** said that he personally accepted the position that the anæsthetist as a specialist was entitled to choose the drug and method which should be used, but he pointed out that by law it was the surgeon who was responsible if anything happened. The surgeon and anæsthetist must be accustomed to work together and must have mutual confidence in each other's skill. He was a warm advocate of ethyl chloride given by vapour method for tonsils and adenoids in children (having had over 17,000 cases at the Royal Infirmary with only one fatality in 15 years), but not adults. He did not consider that by it sufficient relaxation of the muscles of the palate could be obtained to give the operation by the reverse tonsilotome a fair chance. Even for ethyl chloride he considered full preparation as for a major anæsthetic was essential. He had noticed reference in American literature to abscess of the lung following operations for tonsils and adenoids, which might be ascribed either to dropping a piece of tissue down the larynx or perhaps merely to the expression of septic fluids from the tonsil at the moment of removal. He personally had never experienced this sequela, but would be glad to know whether any of the members of the Society had heard of such cases.

The **PRESIDENT** said that as regards the point between heroin and morphia, he did think heroin produced less after-effects. He had had, however, very good results with "Abbott's H.M.C." preparation of morphia, and desired to know whether other members considered this preparation had any special advantages. He thought that intrapharyngeal anæsthesia by the Shipway method, which he employed, was inadequate in many cases as compared with true intra-tracheal, as one missed the return flow of air. He had no special fear of carrying malignant disease into the lung by the catheter, unless the ulcer was very foul, and thought the gain was tremendous over a tracheotomy opening. He agreed that ethyl chloride was inadequate for tonsils and adenoids in adults, using open ether followed if necessary by the Shipway, by nasal tube. For longer dental cases he made extensive use of nasal gas with air. He admitted that the counsel of perfection was to give it with oxygen, but the question of the weight of the cylinders made nasal gas and oxygen hardly practical politics. Admittedly certain cases could not be handled by nasal gas, and he always had a Clover ready. For children under 12, even for dental cases, he found gas, certainly nasal gas, unsuitable, and preferred to rely upon ethyl chloride alone. He regarded 3 c.cm. as the outside dose for a child and with it had only had one serious fright; the child, however, recovered. If 3 c.cm. of ethyl chloride was insufficient he preferred to use closed ether.

Dr. **ROSS** referred to O'Malley's technique for nasal operations, particularly for submucous resection of the septum. Its essentials were the tilting of the head of the table to an angle of 45°, a pillow placed behind the head and neck just down to the upper portion of the shoulders producing a slight flexion of the neck; the use of Phillips's artificial airway to produce strict oral respiration and a combination of local anæsthesia by packing the nose beforehand and continuing with a very light chloroform anæsthesia. Having worked with O'Malley for a short period during the war, he had been struck with the smoothness of events if every one of these details was strictly adhered to. Another point in O'Malley's methods was the use of a very deep nitrous oxide anæsthesia for the enucleation of tonsils and adenoids, even in young strong adults. He agreed with Dr. Gibbs that it was better to produce a deep anæsthesia with gas or gas and oxygen in the first instance, and to use a small dose of ethyl chloride in the last few seconds of the anæsthesia only. He was inclined to think that Guy's original instructions for the anæsthesia were slightly defective in that not enough advantage was taken of the nitrous oxide element before adding the ethyl chloride. With regard to nasal methods, the addition of oxygen enormously simplified the actual administration, but the question of the bulk and weight of the apparatus was so important that he had been specially interested in listening to Dr. Fairlie's experience of nasal gas without special provision for oxygen.

Dr. **FREW** said that with regard to septic lung trouble after operation, he had had two personal experiences: one was a lung abscess following the extraction of very septic teeth—no solid foreign body was ever detected in the lung and the patient eventually recovered. In another case septic trouble followed a piece of bone inhaled during an operation upon the antrum; lung abscess followed, the bone was ultimately coughed up, and here also complete recovery followed.—Dr. **BARRAS** said that he used ethyl chloride extensively among children and did not consider that there was in its use any very material after-sickness.—Dr. **TORRANCE THOMSON** alluded to the impossibility of proving that the addition of ether increased the safety of ethyl chloride; how could you prove it if you had to wait for 30,000 cases before you got your first death after ethyl chloride alone? The further question arose, however, of whether it improved the anæsthesia in type and duration. There was a belief among some people that it did. With regard to tonsils and adenoids in adults, he described Rood's method of saturating the patient with ether given from the open mask much overlaid with towels and blankets. In Rood's own hands the results seemed to be excellent.

Dr. **GIBBS** replied generally to the discussion. He was of opinion that chloroform should not be given after adrenalin. With regard to the sickness after ethyl chloride, he believed that there was a good deal but that it often came on later when the patient had left the dentist's house. Even apart from sickness there was undoubtedly a good deal of malaise and feeling of depression. He therefore gave the smallest dose possible.

At the close of the meeting Dr. **TORRANCE THOMSON** demonstrated the Pinson bomb and the intra-tracheal apparatus devised for use with it. He also showed Mr. N. Dott's intra-tracheal apparatus.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

Early Active Movement in Relation to Fractures of the Upper Extremity.

A SPECIAL meeting of this Society was held on May 22nd, Dr. G. M. **DUNCAN**, the President, in the chair, when Mr. J. W. **DOWDEN** (Edinburgh) gave a lecture on this subject. After referring to the frequent occurrence of these fractures, the anxiety experienced by both practitioner and patient for a good result, and the possibility, always present, of an action against the practitioner for malpraxis in the event of a bad result, Mr. Dowden emphasised especially the importance of a method of treatment which would lead to early recovery of function—a point of the utmost importance to the wage-earning patient, the insurance societies, and in the long run to the State. The longer the limb was kept in absolute immobility—e.g., by splints—the longer would restoration of function take, as the repair had proceeded on restricted lines. Briefly expressed, Mr. Dowden's treatment consisted in first making an effort to get the bones into good alignment, putting the arm into a sling, and giving heroin for the first few nights. As soon as possible, preferably in 24 hours, active movement should be begun, and, later, passive movements carried out by the patient, all joints of the limb being moved, and the movements always stopping short of pain. The arm should be allowed out of the sling for frequent periods during the day. In certain cases a splint might be used at night. The treatment should always be directed towards a good functional result rather than a perfect anatomical result, the chief consideration being paid to the muscles and joints, not solely to the fractured bones. Consequently in children even marked bony deformity could be ignored, as in time superfluous bone tissue and callus would be absorbed and alignment of the limb restored. Mr. Dowden detailed the precise methods used in the individual fractures at the common sites of the upper limb, illustrating his methods and results by numerous lantern slides of radiograms and photographs of patients. He then summarised the points of his treatment, of which he had had over 20 years' experience; the great principle was active movement, and the chief advantages were its simplicity, economy, and rapidity and excellence of result.

An animated discussion followed, in which there took part Mr. Alex. Mitchell, Mr. W. Anderson, Mr. G. H. Colt, Mr. F. K. Smith, Dr. J. Smith (Peterhead), and Dr. J. E. Skinner (Skene). Questions were asked, and Mr. Dowden replied.

Reviews and Notices of Books.

GOITRE.

A Contribution to the Study of the Pathology and Treatment of the Diseases of the Thyroid Gland. By F. de Quervain, Professor of Clinical Surgery in the University of Berne. Translated from the French by J. Snowman, M.D., M.R.C.P. London: John Bale, Sons and Danielsson, Ltd. 1924. Pp. 247. 21*s.*

The genius of Kocher and the extraordinary incidence in Switzerland of enlargements of the thyroid have combined to give Berne a unique position in regard to the surgical treatment of goitre. The tradition has been carried on by Prof. de Quervain, whose name is already a household word in many fields of surgery and whose latest book is a masterly treatise on the subject. Characterised throughout by profound thought and wide scholarship, it teems with practical suggestions of real value.

One has to visit Berne to realise the gravity of the problem presented by goitre to the Swiss nation, but it is a sufficiently startling fact that of children of 16 in the schools of Berne 94 per cent. show some enlargement of the thyroid, whilst 15 per cent. have nodular goitres. Goitre in Switzerland is generally associated with a lowering of the thyroid secretion, resulting in extreme cases in cretinism. The cretin problem alone is a serious one for the country, for it means that a large number of the inhabitants must be cared for by the State, whilst every family is overshadowed by the possibility that an apparently healthy child may gradually reveal this terrible defect. In England the reverse is the case, thyroid enlargement being frequently associated with symptoms of secretory excess, and it has to be remembered throughout the book that in its author's experience only 5 per cent. of goitres were of this class. One of the most suggestive chapters is on the pathological physiology of the thyroid gland, and one cannot but be struck by the stress laid on the investigation of the metabolic rate as measured by the respiratory exchange. The relations between this, the histological structure, and the iodine content of the gland are presented in a very remarkable manner, and a clear outline is given of a problem of extreme complexity.

The diagnosis of goitre in its many varieties is elucidated by a splendid series of photographs and radiographs. As regards the latter, a most valuable point is made of the importance of an accurate study of tracheal compression, as regards site, direction, and degree. A glance at the tracings given should be enough to convince any surgeon of the reality of the danger to which the trachea may be exposed unless it has been previously located. In view of this it is somewhat remarkable that intra-tracheal anæsthesia has made so little headway in Switzerland and it is not even referred to by the author. Many surgeons in this country would regard it as the method of choice, both from its intrinsic safety and convenience and from the facility it gives to the operator. On the other hand, we in England make too little use of the advantages of local and regional anæsthesia, and there are few of us whose technique will not be benefited by a study of the methods described by the author. In the hands of Swiss surgeons these methods have provided the foundation of an exact and beautiful technique, remarkable for the absence of bleeding and the perfect exposure which it affords. But here again the contrast between the hypothyroidism of their patients and the frequent hyperthyroidism of our own has to be taken into account. On the technical side different methods and degrees of removal are fully described, and the difficulties and complications which may arise are considered. The author's method of ligating the inferior thyroid artery is of special value, and we have found by personal experience that it is safe, rapid, and easy. The whole question of ligating the arteries is well discussed, and precise directions are given for the avoidance of the parathyroids and the recurrent nerve.

The book is intended for those, both physicians and surgeons, who are specially interested in diseases of the thyroid gland. It presents in a small compass an immense amount of new and valuable information, gathered from the vast experience of the author. It is lucid and concise in expression, admirable in arrangement, and really well illustrated; whilst the translation by Dr. Snowman is so perfect that it is difficult to realise that it is not the author himself who speaks. To those of us who know the author there could be no higher praise. Prof. de Quervain has given us a book which will be read and re-read by all who are interested in the thyroid.

SURGICAL PATHOLOGY.

By Joseph McFarland, M.D., Sc.D., Professor of Pathology in the Medical Department of the University of Pennsylvania. London: H. K. Lewis and Co., Ltd. 1924. Pp. 701. £2 2*s.*

This book is written on somewhat novel lines. Unhampered by convention, the author has felt free to choose what subjects he would consider and what proportion of space he would assign to each. Inasmuch as Prof. McFarland has written for those beginning to specialise in surgery, his book will, no doubt, serve a useful purpose; but the choice and arrangement of the subjects dealt with make it doubtful whether it will be equally helpful to the ordinary medical student. There is, for example, no systematic consideration of inflammation, infection and immunity or surgical bacteriology, nor are these subjects dealt with really adequately in the section on special pathology. This is all the more surprising since the author defines surgical pathology as the bringing together and emphasising of those aspects of pathology which have been found to be of particular interest and importance to surgeons. Surely the diagnosis and treatment of processes of infection are of the utmost importance to the surgeon.

The book is divided into three parts. The first deals very fully with congenital conditions of surgical interest; the second treats of tumours; and in the third the pathological conditions of the various organs and tissues are discussed. In addition to the general index there is a bibliographic index, but since this is arranged in the alphabetical order of the authors' names rather than under subjects, its value is a good deal diminished; it will, however, serve to direct the attention of English readers to the literature of the United States and the Continent of Europe. The book is profusely illustrated and many of the illustrations are admirable; but others are equally bad, and it is to be regretted that some of the figures intended to elucidate the author's long description of the physiology and involution of the breast should be practically unintelligible.

While the surgical specialist will find much in Prof. McFarland's book of interest and value, it can hardly be recommended as a routine text-book for the less advanced student. Certain aspects of the subject are dealt with extremely well, but others of prime importance are omitted altogether or merely glanced at. And it is to be feared that the beginner who relied entirely upon Prof. McFarland's conception of what should constitute the surgeon's pathological equipment, would become conscious in the hour of trial of many gaps in his knowledge.

X RAY THERAPY.

Die Röntgenbehandlung des Uteruskarzinoms. By Dr. HERMANN WINTZ, O. Professor, Direktor der Universitäts-Frauenklinik, Erlangen. Leipzig: Georg Thieme. 1924. Pp. 30, plus 50 unnumbered pages of illustrations. £1 4*s*.

APPARENTLY a desire had frequently been expressed by those visiting the Erlangen Klinik for a description of the exact technique used in the treatment of carcinoma of the uterus. This book is the result. It does not describe in detail the apparatus used or the dosage given, as these have been gone into more fully elsewhere. It briefly refers to the preparation of the patient for treatment with the technical details of this preparation. Next, the copper electrolysis of the growth is described as an essential part of the treatment. Many, of course, will doubt its value. The book then comes to the part of the subject with which it is mainly concerned—viz., focusing the tube on the growth with all the attendant factors. This last part is illustrated by 50 clear and helpful plates, which leave little to be desired. In fact, these plates form the chief feature of the book, as they occupy more than half of its space. Finally, the after-treatment of the patient is described.

The author has written the book in the hope that it will help others to base a sound technique of their own, feeling there will be variations made by every practitioner to suit his needs. It certainly is a clear and simple description of the Erlangen technique for the treatment of carcinoma of the uterus, so far the most successful field of intensive therapy. It will help those who desire to know the Wintz exact method and can read German. The pictures might even help those who cannot.

Röntgentherapie, Oberflächen- und Tiefenbestrahlung. Sixth edition. By Dr. H. E. SCHMIDT. Rewritten and enlarged by Dr. A. HESSMAN, Dirigierender Arzt der Röntgenabteilung des Krankenhauses am Urban, Berlin. Berlin: August Hirschwald. 1923. Pp. 280. $1.95.

THIS type of text-book of X ray treatment seems to be turned out in considerable numbers in Central Europe. It contains a physical part which is competently written; it then goes on without inspiration, but with care to describe the technique of superficial and deep X ray treatment. This, of course, has all been done before somewhere else, not better perhaps, but often as well. Chapters are put in which deal with the problems of the day such as "Die Hygiene im Röntgenzimmer," in which the illuminating information that the room must have bright walls and not be darkened is given. It is all true and perhaps necessary. Then comes an astonishingly long list of all the diseases which can be more or less successfully treated by X rays. It is, perhaps, as well not to quote some as each disease no doubt has its X ray advocate, but the list taken altogether shows either great powers or great faith. The book is a sound one, helpful to the student of X ray treatment. It gives him a good foundation on which to work and useful practice in reading German.

INFECTION, IMMUNITY, AND BIOLOGIC THERAPY.

With special reference to Immunologic Technique. A Practical Text-book. Third edition. By JOHN A. KOLMER, M.D., Dr. P.H., D.Sc. (Hon.), Professor of Pathology and Bacteriology in the Graduate School of Medicine, University of Pennsylvania. With an introduction by ALLEN J. SMITH, M.D., Sc.D., LL.D., Professor of Pathology in the School of Medicine of the University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 1210. 60*s*.

To call this book monumental would be to do less than justice to the author; for the term connotes finality and immutability—the last of the attributes that Prof. Kolmer would claim for his work or that its admirers would wish to see in it. Enduring as brass, however, it undoubtedly will be; one might even prophesy that a century from now, along with "Gray" and other medical classics, it will still be running into new editions. It would be unprofitable to speculate as to how much of the present matter will still find place in those future editions, but if unremitting and assiduous toil is to find its due acknowledgment, the name of Prof. Kolmer will still figure upon the title page.

The book is so well known to all practical pathologists and bacteriologists, that once the fact that a new edition has appeared and that it fully comes up to the standard of all its predecessors has been noted, little remains to be said. As in previous editions, the author has taken the greatest pains to bring his matter up to date almost to the hour of the final impression. Much that is new since the appearance of the last edition six years ago has been added; the additions are interesting as indicative of the advance made during those years in the theory of immunity and in its practical application. It must be admitted that the great movement initiated by the work of Bordet, Ehrlich, and others does not now advance so rapidly as of old, although it can hardly be said to have lost its force. The principal applications of immunologic therapy in which notable advance has been made since the last edition are the Schick reaction for diphtheria with the toxin-antitoxin method of immunisation of Behring, the technique for the transfusion of blood, the recognition of the existence and significance of the blood groups, and the diagnosis and treatment of the allergic conditions. Of these, the Schick reaction marks a real advance in preventive medicine; this subject is well discussed, and full details are given for the performance of all the necessary procedures. Here, as in all other sections of the book, Prof. Kolmer has not allowed his enthusiasm to run away with him, and clearly points out the dangers inherent in the immunisation process—dangers which can readily be avoided with proper care, but which are none the less very real. In the section on blood transfusion full directions are given both as to the indications for transfusion, the choice of method, and the selection of donors. Sir Almroth Wright's method of immuno-transfusion finds place in this section. In the chapter on isohæmagglutination, though bulk for bulk the work on this subject done in America vastly outweighs that done in this country, it is pleasant to observe that Prof. Kolmer has accorded full recognition to the observations of English writers. Chapters XXIX.–XXXII. are devoted to the clinical allergies, and here again the author maintains an attitude of commendable discretion. In Chapter XXXIX., the principles, such as they are, of non-specific protein therapy are fully dealt with, and there appears to be hardly a use to which this peculiar form of medication has been applied and recorded which has escaped the author's notice. As to the matter included, the author might with advantage have been rather more drastic; a certain number of observations which have been discredited since the last edition still find a place in his pages, and do not help the general flow of the argument; a notable example of this occurs on p. 154. Vaughan's theory of the fermentative nature of the processes of immunity is hardly worthy of such lengthy treatment; the same applies to the schematic representation of the same processes elaborated by Ehrlich; in the light of present knowledge—or lack of it—the time would seem to have arrived when the intriguing pictures of test-tubes full of oddly shaped objects labelled "amboceptor" and so forth might be eliminated from pathological works. However, in face of the immense amount of work, good, bad, and indifferent, incessantly proceeding in all parts of the world, the problem of selection in works such as this must be of extraordinary difficulty.

The book is profusely and intelligently illustrated, and the illustrations, without being works of art, are well suited to fulfil the object for which they are designed. The references are numerous and useful.

SEXUAL LIFE.

The Sexual Life of Man. By Dr. PLACZEK. Translation revised by Dr. W. C. RIVERS. London: John Bale, Sons and Danielsson, Ltd. 1923. Pp. 233. 10*s.* 6*d.*

THIS work is intended to furnish an outline of our scientific knowledge of the sexual life of man for students, doctors, and lawyers, and was originally written by Dr. Placzek, a Berlin neurologist, on account of the difficulty experienced by students in obtaining the larger and better known text-books, which have in many cases gone out of print.

The book starts with a preliminary account of the anatomy and physiology of the sex organs, male and female, and with an outline of the normal history of sex from childhood to old age. This is followed by chapters dealing with genital gland deficiency, the results of castration, and the reciprocal action of the gonads to the other glands of internal secretion. The second half of the book deals with aberrations of the sexual impulse, the various forms of perversion and abnormal sexual impulses being briefly described and catalogued. Although we cannot go so far as Stekel that "In erotic matters there are no normal men," anomalies of the sexual impulse are so commonly met with that it is certainly necessary for every practitioner and lawyer to have some knowledge of this subject, and to those requiring a concise account of the commoner abnormalities Dr. Placzek's book will be useful. Indeed, in the English language there are few other works (with the notable exception of the classical works of Havelock Ellis) to which the student can resort for information, the subject not being one that appeals to English authors or publishers. While this book should therefore be of considerable use in this country, it contains many statements which are open to criticism. We consider the author's references to the work of Freud and of Jung unnecessarily scathing. It is true that fanatics of these creeds are commonly met with, but it is equally true that both Jung and Freud have made valuable contributions to our knowledge of the sexual life. Again, in the latter part of the work we find a reference to treatment by means of transplantation of human testicle. For this purpose cryptorchid testicles are recommended partly on the grounds that they are rich in interstitial cells, and partly because having no reproductive function they cannot transmit hereditary qualities! This, of course, implies that the transplanted testicle can function with respect both to internal and external secretion, and is an error of a very elementary nature. However, in spite of these deficiencies the book will be of use to those requiring a concise and at the same time comprehensive survey of the subject of the sexual life of man.

Sexuological Essays. By W. C. RIVERS, M.R.C.S., L.R.C.P., D.P.H. Leipzig: Curt Kabitzsch. 1924. Pp. 168. 7*s.* 6*d.* (Circulation limited to Medical Practitioners.)

IN this book Dr. Rivers shows his boldness when he announces that, for obvious reasons, he failed to find a publisher in England or America. He shows how various present-day movements, that for the prevention of venereal disease, for example, justify the study of sex on the ground of practical needs, but that there is still a strong opposition which denies to science the right to investigate it. After a chapter giving an outline of the sex instinct and its common anomalies, Dr. Rivers goes on to such varied subjects as kissing and its related actions, the homosexuality of Walt Whitman, masculine affection for cats, and the result of race miscegenation. The chapter on "medical women in the future" is anti-feminist, and he gives the impression of finding always the evidence he would like, as, for instance, when he says (p. 64) that particularly few women qualify in the minimum time because their health is not so constant as that of men. The book is stimulating, and the author is sure to meet with strong disapproval, for which he seems to be prepared.

MEDICAL AND VETERINARY ENTOMOLOGY.

Second edition. By WILLIAM B. HERMS, Professor of Pathology in the University of California; Consulting Entomologist for the California State Board of Health. New York: The Macmillan Company. 1923. Pp. 462. 28*s.*

THIS book is intended as a text-book for use in schools and colleges as well as a handbook for physicians, veterinarians, and public health officials—ambitious objects involving a uniformly high standard of work. The author's treatment of the various branches of entomology, especially where it affects man, is, however, unequal, while veterinary entomology is described in a palpably inadequate manner. The economic annual loss to the United States caused by insects is estimated by the Department of Agriculture at 800 million dollars and the vital loss at 348 millions, whereas it is solely with the latter aspect that this volume deals. The introductory portion, the little sallies into helminthology and protozoology, are excellent in so far as they constitute a historical record, but here the serious student of tropical medicine will find statements which are not generally accepted: as, for instance, Adie's account of the development of leishmania in the bed-bug (p. 7). The various families of insects are not described in detail. We note that the terms definitive and intermediate host, though correctly defined, are not strictly adhered to throughout the book. The unequal treatment of the various parasitic genera calls for some comment. The house-fly and its habits are treated at very great length, while a description of the important genus *Glossina* is crowded into less than half a page. Such popular terms as "roaches" for cockroaches, and "wrigglers" for mosquito larvæ would seem out of place in a scientific work.

We have nothing but praise for the chapter on parasites and parasitism; the definition of the various terms employed and the correlation of comparative protozoology, helminthology, and entomology are too seldom attempted in books of this description. If only for this chapter the book is well worth having.

LOVE IN CHILDREN AND ITS ABERRATIONS.

A Book for Parents and Teachers. By **OSKAR PFISTER**, Pastor in Zurich. Translated from the German by **EDEN** and **CEDAR PAUL**. London: Allen and Unwin. 1924. Pp. 572. 24*s*.

Pfister writes this book for the lay public, and the reader acquainted with his previous works will find himself covering a good deal of familiar ground. The author opens with an historical survey showing how love was treated as an important factor in human relations till the advent of scientific psychology, the attitude of which he illustrates by the observation that in the chief works of Wundt, the most highly respected psychologist of our day, there is not a word about love. To this attitude he ascribes it that scholasticism has "provided nothing of value for pedagogy, psychiatry, criminology, or the conduct of life." In his own studies he claims to restrict himself to the data of personal observation, and justifies his claim in so far as he freely provides histories of actual cases, treated by analysis, which supply a foundation for deductions and generalisations. One is nevertheless occasionally tripped up by such phrases as "it is obvious that" when the deduction is anything but obvious to the non-analytical reader. The book indicates the operation of family influences in producing neurotic disturbances and abnormalities through their effect upon the love impulse, and the application of psycho-analysis in unravelling the factors concerned. Most of his conclusions are derived from the analysis of adolescents and adults, and for an account of a child analysis Pfister falls back upon Hug-Hellmuth, whose description (p. 536) makes the analysis a trivial and unconvincing affair.

Notwithstanding a tendency to exhortation and the indifferent English that occasionally appears ("goods" as the plural of the abstract noun, for example), the book must be placed among the serious works on the subject. It conveys a large amount of important information of a kind not found in usual writings on child-life and development.

JOURNALS.

QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.—The current part of this journal contains six memoirs dealing with various topics, including both vertebrate and invertebrate anatomy and histology. Prof. Brontë Gatenby leads off with an account of the Transition of Peritoneal Cells into Germ Cells in Gallus Bankiva, which is illustrated by one coloured plate and two process blocks in the text. The author shows that sexual cells are formed de novo, as was originally believed to be the case, from the peritoneal epithelium and not handed down from original germ cells segregated at the first division of the ovum. Both ways of formation of ova and testicular cells are to be met with in the animal kingdom, though present views on the continuity of the germ-plasm would seem to argue the original segregation as the older way. Dr. Gatenby, however, is convinced, and quotes facts due to the investigations of others as well as those discovered by himself in support of the twofold mode of origin.—In another paper Dr. Bahl continues his investigations into the nephridial system of earthworms. It should be pointed out, however, that although this naturalist has added a great deal to what is known upon this matter, he did not "discover" the existence of nephridia in the oligochæta which open into the enteron. This was found more than 30 years ago, and is recorded in Vol. XXXIII. of the journal under review.—A second memoir upon an oligochæte worm is also from the pen of a native of Hindustan, and deals with the development of the generative system of the aquatic worm Stylaria.—Other contributions include two by Mr. de Beer in the development of the head in heterodontus, and one on the skin of mammals, by Mr. Shapiro.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XVII.—EQUAL PAY FOR EQUAL WORK.

BY FLORENCE E. BARRETT, M.D., M.S. LOND.,
PRESIDENT OF THE MEDICAL WOMEN'S FEDERATION.

ONE feature of the modern development in preventive medicine is the increasing number of full-time posts with definite salaries offered to qualified medical men and women. At the same time there has grown up within the medical profession a more or less pronounced professional trade unionism, which probably had its birth consciously or unconsciously in memories of the undignified position endured by doctors under the old club system, and in the fear that unless the medical profession itself fixed an adequate scale of salaries, which its members should honourably uphold, public bodies would whittle down remuneration to the minimum which would still attract applicants.

A High Standard for the Public Health Service.

The medical profession as a whole have agreed that £500 a year is the minimum that should be paid for whole-time work by a fully qualified man or woman. In the public health service a higher minimum has been fixed, coupled with a recommendation that no one should be appointed to these important posts who has not done at least three years post-graduate work of a kind which would qualify the candidate to fulfil adequately duties which have so potent an influence in preventive medicine. There is still some confusion in the minds of professional men and women with regard to the two different minima. It is not very long since £500 a year was fixed with the approval of the profession as being adequate pay for full-time appointments, and the more recent pronouncement that £600 a year should be the minimum accepted for public health posts is still unknown to many, while the reason for the different standard is obscure to others.

To the general public—including some who are holding positions on public bodies—the higher scale claimed in the public health services is merely an attempt of one branch of the profession to obtain higher salaries: they have not begun to realise that in the interests of the whole community it is wise to ensure that experienced people only should be appointed to these posts. This lack of understanding will only be remedied if all public health authorities responsible for appointments are induced to make it quite clear in their advertisements that application will only be accepted from candidates who have fulfilled the condition of at least three years' suitable post-graduate work. Only in this way, too, will the younger members of the profession learn that it is in the interests of the nation as a whole that responsible posts should be the reward of experience gained, and therefore that the remuneration is justifiably fixed at a rate which to some of the newly qualified seems unnecessarily high.

Partly arising from the failure of public bodies to advertise for graduates of three years' standing, and partly from the fact that just now the numbers of medical students of both sexes which filled our medical schools at the end of the war are qualifying and adding to the names on the Medical Register with unusual rapidity, a crisis is arising in the profession which is very serious for its future, and which will strain to the utmost the patience and loyalty of both men and women if it is to be successfully dealt with.

Sex-limited Advertisements.

The first attempt on the part of those responsible for public health offices to avoid the higher scale of salary has been to issue advertisements without conditions of experience for medical women at £500. Many women applied for these or asked for particulars in complete ignorance of the fact that £500 a year was not recognised by the profession as an adequate salary. To all whose names were known, the Medical Women's Federation wrote acquainting them with the facts, and numbers of women to whom a post at £500 a year would have been a coveted prize did not apply, an act of self-sacrifice which all will recognise. Some had accepted posts* before knowing that it was below the professional standard, and had involved themselves in financial responsibility. In this way the present crisis has arisen which, put quite plainly, is an attempt to offer a lower scale of salaries to women in the profession than is offered to men for the same work.

The unfairness of such an offer is unnecessary to dwell upon in a medical journal. All know that the course of training, the diplomas taken, and the work done in public health appointments is the same for women as for men, and therefore any attempt to pay them less is a serious injustice. What we all have to recognise, however, is that it is impossible to lower the standard of pay given or the experience demanded from any one group in the profession without creating profound changes of one kind or another. There is no doubt that women will do the work as well as their male colleagues, and if women accept lower salaries the authorities will be quick to recognise that, by employing women, they can obtain as good an officer with economy of expenditure. The immediate result will be that all other local authorities will follow suit, and women will obtain the majority of the posts. The other alternative result would be that men would also accept posts at the lower standard—the facts suggest that they are as likely to succumb to the difficulties of their circumstances as women—and any attempt of the profession to fix its own standard, either for men or women, would be frustrated.

What there is at Stake.

There is, therefore, at the present time a need for the utmost loyalty from every member of the profession, because what is at stake is not merely a question of money, but the right of the medical profession, who are trained in matters which pertain to the health of the community, to advise as to the experience necessary in health officers, and the salary which can reasonably be expected to attract the right people. At first sight it may appear that the only question involved is the loyalty of women, and that their duty is simply to refuse posts in the public health service at less than £600 a year. But if under such pressure of refusal public authorities are obliged to raise the salary, and the same post under the more favourable conditions is then thrown open to men only, are men to feel free to supplant the women whose loyalty has won the battle in that particular instance? Again, should medical men feel justified in working under a public authority which openly announces its intention to pay medical women at a lower scale than medical men for the same work?

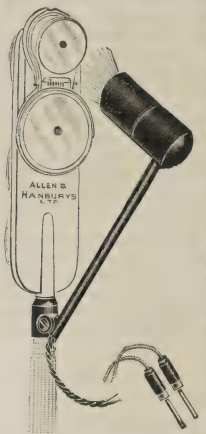
In fact, the question before the profession is, Are medical men and women to be mutually loyal in this crisis to the decisions of the profession as a whole, or is loyalty to be only on the side of the group chosen for attack? This question needs serious thought from all, because it must frankly be acknowledged that women cannot win this battle alone. If the posts they refuse can be immediately filled by men, their resistance will clearly mean the gradual exclusion of women from the public health service. Without the assistance of their men colleagues women would be obliged to give in, and we should probably find that some individuals will accept posts they desire for the sake of the experience it gives, and because they know that in certain branches of the public health services women are specially needed.

There is no doubt, however, that with the loyal assistance of the profession as a whole, individual women would be prepared in the future to sacrifice personal gain as they have done so often in the past, and thereby to retain for the profession the right to advise as to the conditions of service which should be offered in order to secure experienced doctors in posts where experience is necessary for the public weal. The Medical Women's Federation, which includes 900 women in practice, and many hundreds of associate students, is still unanimous in believing that equal pay for equal work should remain the standard in the profession, as it has always been in the past.

It is possible, however, that all men at the moment do not realise how vital a blow will be struck at the prestige and influence of the whole profession if this standard is not maintained.

New Inventions.

OPHTHALMOSCOPE ATTACHMENT.

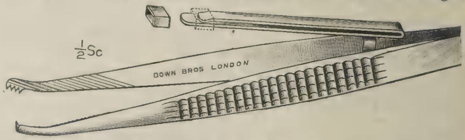


OWING to the difficulty which many students and practitioners experience in performing ophthalmoscopic examination by the direct method with a Morton's ophthalmoscope, and owing to the expense entailed by the purchase of an electric instrument, we have devised (see figure) a simple attachment for the ordinary ophthalmoscope, by means of which it is possible to obtain the advantage of the electrical instrument at a comparatively small cost. The apparatus consists of a collar and an adjustable arm with a lamp-holder, which is fitted to the ophthalmoscope at the junction of the handle and the body. The electrical part is of the simplest, being merely a pocket battery, flexible wire, and a flash-lamp bulb. At a slight additional cost a variable resistance may be obtained. Messrs. Allen and Hanburys, Ltd., Wigmore-street, London, W., are the makers of the instrument.

W. O. C. JARRATT, M.R.C.S. Eng.
LEONARD P. LOCKHART, M.B., B.Ch. Camb.

A NEW MAGAZINE FOR MICHEL'S CLIPS.

THIS instrument, which is a combination of Childe's forceps with a fixed magazine, has proved very satisfactory in use. Its main advantage is that by virtue of the special serrations at the end of Childe's forceps it is quite easy to secure eversion of the skin edges and maintain it whilst introducing the clips. An additional advantage is that it is so constructed that the magazine when in use lies parallel with the skin and the clips are drawn off from the lower end instead of the upper as in Bonney's instrument, a fact which brings the clips closer to the wound and makes for more rapid application. A special metal cap is also provided, which fits over the end of the magazine and prevents the clips from slipping off during sterilisation or while being carried in the surgeon's bag. I feel sure that those surgeons who use Michel's clips will find this magazine a useful addition to their surgical equipment. The instrument is made by Messrs. Down Bros., St. Thomas's-street, London, S.E.



Birmingham. BERNARD WARD, F.R.C.S.

---

* It is only fair to say that although some advertisements for junior whole-time appointments asked for women only, the numbers of men and of women respectively who have *accepted* underpaid posts are about equal.

THE LANCET.

LONDON: SATURDAY, JUNE 21, 1924.

HOSPITAL SUNDAY.

THE annual collection for the Metropolitan Hospital Sunday Fund will take place next Sunday, June 22nd, and it is not necessary to press the urgency of the appeal upon our readers. They are all fully aware of the conditions of debt and mendicancy under which many of our splendid voluntary institutions are compelled to carry on their work, and the general public know well that the situation is often a terribly anxious one. The fear is lest the appeal of the Fund should have become over-familiar. No more mis-used text was ever written than "Ye have the poor always with you," so easily can it be dislocated from its context and applied as a defence for inaction.

The methods which the hospitals most usually employ to obtain the support necessary for their conduct have become stereotyped, and though the totals of the annual collections give no reason to think as yet that these methods have lost their influence, still it is well that they should be reinforced by the support that comes from large consideration of hospital questions by representative citizens. There is now much opportunity for the general public to become alive to the real position of our voluntary hospitals, and also to appreciate the thoughtful and vigorous manner in which it is being dealt with. The Voluntary Hospitals Commission have just held a conference at which full facilities were given for reporting the proceedings; and this meeting was itself consecutive to a largely attended conference of medical, labour, and kindred organisations which met less than two months ago at Caxton Hall, Westminster. At this meeting general questions of hospital administration and control were fully discussed,[1] with the result that the Minister of Health asked the Voluntary Hospitals Commission to report to him upon the whole matter of additional hospital voluntary accommodation required in England and Wales and on the best means of providing and maintaining it. The discussion in the conference chamber of the Ministry of Health will show to all how vital to the national interests a sound provision of hospitals has now and admittedly become. And as we go to press the fourteenth annual conference of the British Hospitals Association is being held in Victory House, Leicester-square, under the presidency of Sir ARTHUR STANLEY. The relations of the voluntary hospitals to municipal authorities and to approved societies form the essential programme of this meeting, so that the important place in the whole of society occupied by the institutions will become apparent. Thus the functions at the close of this week form a fitting prelude to Hospital Sunday, for the real conditions under which financial stress and shortage of beds are endured will become clear to the public from the experience of different authorities, who will be able to make the statements of business men, and to appeal for hospital support on grounds of hard reason.

Not a word will be uttered which cannot be considered an argument for a generous response to the Hospital Fund. The subscription list of the Hospital Sunday Fund makes its more particular appeal to the ordinary householder, and neither he nor the members of his household are likely to forget the high prices of things necessary to daily life, the weight of taxation, and the depressing difficulty of making both ends meet. But if the Fund, through the stress of the times, loses old friends it should gain new ones on whose ears perhaps the arguments of scientific sociology may fall with a clearer message than any references to altruistic sentiment. Yet the grand message must remain that those who have should help those who have not. And still the plight of the suffering sick will draw response from the more fortunate. There is reason to hope that the Hospital Sunday Fund for 1924 will show a great return. The appeal is being made to a public which is becoming really informed.

NEW WORK ON THE ÆTIOLOGY OF SCARLET FEVER.

RECENT work in America encourages the hope that the cloud of uncertainty which has so long enveloped the ætiology of scarlet fever is at last to be lifted, and that not only has the causative micro-organism been identified, but that we shall soon be in possession of effective means for the treatment and control of the disease. Last autumn Drs. GEORGE and GLADYS DICK [1] reported that they had been able to communicate the infection to a human subject by swabbing the throat with a culture of a hæmolytic streptococcus obtained from scarlet fever patients. In January they announced that they had succeeded in producing scarlet fever in another volunteer, on this occasion employing a different strain of the same micro-organism. As a control for this experiment they selected an individual who, having given a negative skin test, was presumably not susceptible, and this subject failed to develop the fever. The skin test employed, consisting of the intra-cutaneous introduction of 0·1 c.cm. of a diluted filtrate of the hæmolytic streptococcus and already known as the "Dick test," appears, like the analogous Schick reaction in diphtheria, to be positive only in susceptible persons.

In the investigation of their eponymous reaction Drs. GEORGE and GLADYS DICK [2] found that it was absent in 62 out of 65 scarlet fever convalescents, and also negative in 15 out of 16 individuals who had suffered from scarlet fever at some previous date, whereas 41 per cent. of persons who gave no history of having had the disease were positive reactors. These results have been confirmed by C. F. BRANCH and F. GILL EDWARDS,[3] who report that all the convalescent patients whom they tested, 65 in number, gave negative reactions, that three patients acutely ill with scarlet fever gave slightly positive results and became negative in convalescence, and that 40 per cent. of individuals with no history of scarlet fever, a percentage practically identical with that of the DICKS, were positive. Control tests with heated filtrate were consistently negative, and they conclude that the Dick test apparently has a specific relationship to immunity to scarlet fever. A similar view is expressed by A. ZINGHER,[4] who has made a very complete investigation of the reaction, and finds the susceptibility by age-groups from birth to adult life corresponds closely to the percentage susceptibility to diphtheria as shown by the Schick test. This observer also noted positive reactions in the acute stage of the fever in all but three of nearly 100 cases examined, the patients giving negative results as they progressed into convalescence. Immunisation experiments with the streptococcus toxin have also been carried out by the Dicks[5] and by Zingher. Susceptibles when injected with suitable quantities of the filtrate may develop a scarlet fever rash with nausea, vomiting, and pyrexia of 48 hours' duration. After subsidence of these symptoms the skin test is found negative or slight. The effects appear to be produced rather by a soluble toxin than by a filtrable virus, as the incubation period is less than that of experimental scarlet fever, and, moreover, the filtrate shows resistance to a temperature which is sufficient to kill bacteria.

[1] Jour. A.M.A., Oct. 6th, 1923.
[2] Ibid., Jan. 26th, 1924.
[3] Ibid., April 19th, 1924.
[4] Proceedings of the Society for Experimental Biology and Medicine, 1924, xxi., pp. 293–298.

The Dicks[5] now report that they have succeeded in obtaining a specific antitoxin. They have immunised a horse by subcutaneous injections of sterile filtrate from broth cultures of the strains of streptococci that had produced experimental scarlet fever. The serum of the animal was first tested by being mixed with various dilutions of toxin, and it was found to be incapable of neutralising even weak dilutions. After increasing doses of toxin, up to 250 c.cm., had been administered, the horse's serum neutralised strong dilutions of toxin. This antitoxin was not destroyed or lost in the process of concentration. The authors conclude that its therapeutic value can only be determined when the results of its use in a large number of carefully controlled cases are available, and it is to be hoped that no time will be lost in submitting the antitoxin to such a trial. Notwithstanding the work of Klein, Mervyn Gordon, and others, many competent authorities have been inclined to regard the streptococcus more as a secondary invader, responsible merely for the septic manifestations of the disease, than as the causative micro-organism itself. In the light of these researches it looks as if such a view of the question requires revision. A very strong case has been made out for the hæmolytic streptococcus of the Dicks, and it is difficult, with the analogy of diphtheria before us, to question the specificity of a toxin which gives such results as have been mentioned above. Now that an antitoxin has been produced the employment of toxin-antitoxin mixtures bids fair to be a success, but it is obvious that time is required before we can have any real assurance that the control and treatment of scarlet fever will be on the same level as that of diphtheria. It may be added that the research was made possible by a large donation from Mr. Harold McCormick, of Chicago, who had lost a child from scarlet fever.

◆

THE DIAGNOSIS OF TUBERCULOSIS IN PENSIONERS.

A striking and noteworthy outcome of the campaign against tuberculosis in this country is the recognition of the fact that diagnosis is often a problem of great difficulty, involving, in some cases, skilled observation of the patient over a matter of days or weeks along with expert consideration and appraisal of clinical, pathological, and radiological data. This is now officially recognised by the tuberculosis and pensions authorities. It is important that it should be more widely appreciated by the public generally, since too frequently patients and their friends expect from a single clinical examination a definite opinion as to diagnosis, prognosis, and treatment. The complexity of the problems involved is admirably illustrated by the interesting paper, published in our issue of last week, by Dr. Alexander Sandison and Dr. Basil Price, of the Ministry of Pensions. At the outset they point out the special importance of accurate diagnosis from the point of view of the pensions authorities, especially in relation to their decision on the question of entitlement to pension. It is obviously of importance that this should be arrived at with full justice to the man claiming, but without detriment to the State. As long ago as 1920 the Ministry arranged for 100 cases, taken at random, of men pensioned for tuberculosis to be subjected to a comprehensive expert examination. It was found that about one-third were wrongly diagnosed as tuberculosis. In consequence of this, special arrangements were made for the observation and investigation of doubtful cases of tuberculosis amongst pensioners. The period of observation is limited to 28 days, but the average time taken is three weeks.

The observations recorded in this paper were made by Dr. Price upon pensioners in the London region admitted to the special observation beds at the Ministry of Pensions Hospital at Orpington, where 80 or more beds are available for the purpose, with special facilities for laboratory and X ray investigations. He bases his conclusions on 500 cases, of which 243 were regarded as pulmonary tuberculosis with "entitlement" for that condition. Only 37 of the 500 had records of tubercle bacilli having been found, and in only 8 of these were tubercle bacilli actually found while under observation. They were found in 13 of the remaining 206 cases, in which the diagnosis had previously been made on clinical grounds only. The results of the investigation demonstrated that in 9 per cent. of the 243 cases tubercle bacilli were present in the sputum or other secretions, 6 per cent. gave other evidence of activity. 50 per cent. presented quiescent or arrested lesions, while 33 per cent. gave no clear evidence of present or past tuberculosis. It will be noted that the percentage of wrong diagnoses is strikingly in agreement with that in the original 100 cases investigated in 1920. These figures would seem to indicate the need for similar careful observation of cases under suspicion of pulmonary tuberculosis in civilian practice, for there is no reason to suppose that the percentage of error is less in such patients than in the pensioners. The importance of this is indeed recognised by most of the tuberculosis authorities, who provide beds for special observation in chest hospitals and other institutions. It is also of importance in the well-to-do who do not come under the ægis of the official schemes, and it serves to emphasise the necessity for providing more general opportunities for study of tuberculosis in connexion with the medical schools, especially those not having a tuberculosis dispensary affiliated to them. It must be remembered that it is still the general practitioner in the majority of cases who first comes in contact with the patient and upon whom the responsibility of suspecting the disease in the first instance devolves. It is therefore necessary that adequate instruction for both undergraduate and post-graduate students should be provided, as well as means for special investigation of doubtful cases.

In the analysis of the 500 cases passed under observation, Dr. Price refers to the influence of syphilis, gassing, and gunshot wounds of the chest in regard to the incidence of tuberculosis, but no striking or noteworthy facts emerge. On the other hand, his observations on the relative value of clinical, pathological, and radiological evidence in the investigation of suspected tuberculosis are interesting and suggestive. He allows that the complement-fixation test does not yet approach in value the Wassermann reaction in syphilis, though he claims that it may be helpful. He finds that a strong positive reaction suggests a tuberculous infection, but that its degree is not necessarily proportional to the clinical condition or to the activity of the disease. It may also be positive in non-tuberculous conditions, and the presence of a positive Wassermann reaction much impairs any deductions from a positive complement-fixation test unless the latter is of higher value than the Wassermann. Pirquet reactions were usually carried out, but gave no consistent results in regard to the complement-fixation tests; indeed, the observations were often mutually contradictory. Other tuberculin reactions were not employed owing to the possible risk of activating arrested or quiescent lesions. The examination of the sputum for albumin proved not to afford any help in diagnosis either as to the presence of the disease or to the activity when present. In regard to the value of radiographic reports, it is interesting to find that in 127 cases the X ray findings tended to corroborate the positive clinical evidence, while in 66 cases, in which on clinical grounds tuberculosis was diagnosed, the radiographic findings were negative. On the basis of these figures Dr. PRICE urges that the negative results of X ray examination must not be allowed to overweigh the diagnosis made on clinical grounds. He sums up his views on the relative values of clinical, pathological, and radiographic observations in diagnosis by maintaining that apart from the finding of tubercle bacilli the chief reliance must be placed on clinical evidence, a perspective with which most observers who are concerned in the diagnosis of pulmonary tuberculosis will agree. This conclusion serves further to emphasise the importance of the clinical study of this disease by students and practitioners.

NON-POTABLE SPIRIT.

IN accordance with the announcement in the Budget Statement, methylated spirit sold to the general public for domestic purposes has, since May 1st, contained an addition of crude pyridine in order to make it less acceptable as a beverage. The new mineralised spirit will contain, to be exact, crude pyridine 0·5 per cent., wood naphtha 9·5 per cent., mineral naphtha or paraffin oil 0·375 per cent., and methyl violet a trace. The Chancellor was advised that this spirit would be so nauseous and so difficult to swallow as to give pause to the would-be drinker, and if his reluctance were overcome, the draught would make the victim so ill (but not mortally) that he would be unlikely to attempt to defraud the Revenue by continuing to drink it. We learn from the *Chemist and Druggist* that it had been the practice by those who wished to drink the old methylated spirit to remove the petroleum by diluting and shaking the spirit with salt or charcoal. Our contemporary suggests that there is a simple method of separating the pyridine from the new spirit, and it remains to be seen whether the public will find this out or not. Major F. J. W. Porter, writing to us from the Surgical Nursing Home in Bombay, recommends the addition of one half per cent. each of caoutchoucine and pyridine for the denaturing of spirit for surgical purposes. Every surgeon, he says, knows that it is impossible to use tincture of iodine made from methylated spirit denatured by the British Customs, whereas that prepared by the Indian Customs in the way suggested can be used for such a purpose. He can see no reason why the British Excise authorities should not allow hospital spirit to be prepared in this manner, seeing that it is absolutely undrinkable even by Indian fishermen.

Annotations.

"Ne quid nimis."

LOCAL ANÆSTHESIA.

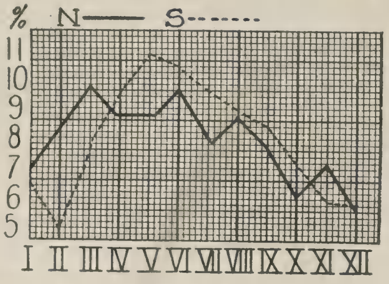
THERE is still a certain amount of rivalry between local and general methods of analgesia in the sense that one or other is more in favour in the practice of most surgical clinics, and a perspective can be obtained only by observing the practice at a number of centres. So much depends upon adequate technique and assistance, and where the arrangements are adapted for the one method things run so smoothly as to limit the demand for the other. Particularly is this the case where an abundant supply is available of highly-trained assistants in general anæsthesia. The growing experience and popularity of local anæsthesia is evident on perusal of the second abstract-review of this subject contained in the June issue of the *Prescriber* (Edinburgh), whose editor, Mr. Thomas Stephenson, D.Sc., F.R.S. Edin., has long made it a practice of collecting and collating information on the borderland of medicine and pharmacy. Attention is called in this review to the unrivalled position still occupied by cocaine by reason of the intensity and persistence of its local anæsthetic action. Novocaine appears to be destroyed by contact with the tissues, and of the series of allied preparations, such as eucaine, tropocaine, stovaine, and alypin, all seem to be harmful in some degree to the tissues surrounding the sensory nerve endings. In the case, however, of stovaine this damage may be slight or even negligible, in view of the remarkable results of 400 operations under spinal analgesia, related on p. 1256 by Mr. B. H. Slater, medical superintendent at St. Luke's Hospital, Bradford. No death in this series could be ascribed to the stovaine employed—the two patients dying on the table being already in a moribund condition—and Mr. Slater can of his own experience cite no disadvantage of spinal analgesia, provided the technique be correct, save the slight extra work which devolves on the surgeon. The advantages speak for themselves. Spinal analgesia is safer than general; it gives rise to no chest complications; the comfort of the patient is vastly increased, so that a stroll through the wards after operation day suggests "a convalescent home" in the case of spinal analgesia, and "the deck of a cross-Channel packet in dirty weather" in the case of general anæsthesia. With spinal anæsthesia the surgeon finds complete muscular relaxation; he has no anæsthetic anxiety; the patient does not suffer from shock and can be consulted if necessary during the operation; the air of the theatre remains pure. General anæsthesia must set its claims very high to overshadow this record. The review in the *Prescriber* alludes to another application of regional anæsthesia, originated by Sellheim in 1905, of which more is likely to be heard; paravertebral anæsthesia consists in blocking the last five dorsal nerves on each side by means of novocaine injection, and has been lauded as the method of choice for operations on the kidney. Of other new local anæsthetics set out in the review, we have already given attention to tutocaine. There remains apothesine, a local anæsthetic of the novocaine type, effective for injection anæsthesia, the solutions not being injured by boiling; and a new substance known as butesin, which in the form of picrate salt combines anæsthetic and antiseptic properties and may fill a useful place in the treatment of burns, ulcers, and other denuded painful lesions of the skin. Surgeons and anæsthetists will be grateful to the *Prescriber* for the readily accessible form in which so much accurate information is given.

ACUTE GONORRHŒA IN WOMEN.

THE treatment of acute gonorrhœa in women, which is discussed on p. 1281, presents certain sociological difficulties not encountered in any other condition except syphilis. The point of most moment is whether or not the patient should be informed of the nature of the complaint, and, if she suspects already, whether the suspicion, when accurate, should be confirmed. There are obvious disadvantages in a bald statement of facts, and one should be guided largely by the history accompanying the case. A newly married woman can acquire an acute infection from a mild and almost forgotten gleet nearly as readily as from an acute infection in the male. Similarly, women after childbirth, or when debilitated, may succumb to an infection which normally might not affect them. Again, a woman can harbour the gonococcus in the cervix, apparently for years, until some fortuitous circumstance precipitates an acute salpingitis. Obviously, there are great difficulties in apportioning blame in these circumstances, and no hard-and-fast rule is applicable. Legally, only evidence of the presence of the gonococcus in smear or culture can be accepted as a positive proof of the diagnosis, although it is well known that the organism cannot be isolated in a large proportion of genuine cases of gonorrhœa in women. The wise course, therefore, would be to treat the condition adequately, and, only if called upon, to pronounce definitely, after bacteriological proof, on the nature of the disease.

SPRING TIREDNESS AS A VITAMIN-DEFICIENCY.

IN a paper illuminated by some instructive statistics, Dr. R. Ehrström,[1] of Helsingfors, has made out a case for regarding spring tiredness not merely as a neurosis, but as an expression of vitamin deficiency. His first graph represents a study of the first attendances during 1921 and 1922 at the University Polyclinic in Helsingfors of patients whose symptoms were exclusively or mainly characteristic of neuroses. There were 3039 such patients whose first attendances during the 12 months of the year are mapped out in the heavy line of the graph. It will be seen that these first attendances were most frequent in the spring—the period when general lassitude is most common. After midsummer the graph shows a rapid fall which, except for two slight interruptions, is maintained till the end of the year. The dotted line represents the monthly incidence of the 5471 suicides committed in Finland in the period 1851–1907. It will be seen at a glance that the profile of the two lines is remarkably similar, and Dr. Ehrström suggests that this similarity is due to identity of the factors responsible for both. Their height towards midsummer might suggest to the casual observer that the sunlight and warmth of the early summer had exercised a deleterious effect on the stability of the nervous system, but this is an explanation which Dr. Ehrström does not accept. The incidence of neuroses between April and August and between October and February was as 9·1 to 7·2, and, in the case of suicides, as 10·1 to 6·5, and these differences were, in his opinion, a matter of accessory food substances or vitamins. The good effects of an adequate supply and the ill-effects of an inadequate supply of these substances would seem to be comparatively slow in showing themselves. In the spring, and even in the early summer, the inhabitants of Finland still suffer from the inadequacy of their vitamin supplies during the winter, and the good effects of an adequate supply of vitamins being also tardy, December finds most persons in Finland still enjoying the benefits of the short summer of Northern Europe. As Dr. Ehrström puts it: "We are well in the autumn after the light and open-air life of the summer, and we feel unwell in the spring after the darkness of the winter and a sojourn within four walls. We live, so to speak, in the autumn and winter on the stored-up light of the summer." The fact that animal life in general suffers from the same handicap as human beings in this matter prevents the inhabitants of Finland from making good the shortage of vitamins in the vegetable kingdom by living on the animal kingdom and its products. Dr. Ehrström's study and the conclusion he draws from it, although going at present a little beyond the facts submitted, certainly stress the value of the accessory food substances and the importance of agencies such as sunlight, for which we have only imperfect substitutes. Let us hope that we may be able in the future to bottle and tap such substitutes at our own free will, regulating them with the precision of the gardener whose reservoirs of water enable him to regard with equanimity a persistently cloudless sky.



N= NEUROSES, S= SUICIDES.

MEDICAL EXAMINATION OF FACTORY ENTRANTS.

THE Association of Certifying Factory Surgeons has issued a report in which adverse comment is made upon the findings of the Home Office Committee on the medical examination of young persons for factory employment. These findings, which were briefly stated in our issue of May 24th, are important in that they deal with the very basis of factory medical service, and are concerned with the examination of over a quarter of a million juveniles every year. Both the report of the Association and the findings of the Committee agree in holding that at present all is not as it should be. Many of the criticisms in the report seem to us to be well founded, and they cannot be readily put on one side, as they express the opinion of those practically acquainted with the present position. Perusal of the findings of the Committee and of the comments of the Association leaves an uncomfortable impression that the Home Office Committee have been more concerned with deciding what department should control the work than with making the work really effective. In their short and hurried existence they did not delve deep or consider the fundamental question how to apply the principles of public health medical service, as undertaken by local authorities, to our factory organisation. The Ministry of Health calls upon local authorities to carry out certain medical duties, the Ministry bears a proportion of the expenses incurred, while it leaves to each authority free choice of medical personnel for carrying out the duties. Local authorities appoint for themselves the doctor who is to inspect their children at school, and who, able to obtain advice from medical experts at headquarters, becomes a trusted adviser on all matters concerned with the health of the local school population. So it is with other branches of the public health service which relies essentially on local acquiescence in sound advice rather than upon compulsory action. This method, for various reasons, has not been followed in factory medical service. Here the factory presents a new grouping of the population, which should, like the locality, have free choice of its medical service. But, in fact, the appointments have been made in London, the fees to be paid have been fixed in London, and revision of the appointments has not been a habit at headquarters. Hence, the factory owner has come to regard the certifying surgeon more as an interfering outsider than as a useful friend. The wonder is not that factory medical service is unsatisfactory, but that it is so little unsatisfactory. This it owes to our national capacity for service even when badly organised. The question is whether the time has not come to revise the factory service on the lines of the public health service, when duties would be imposed by legislation, but the choice of doctor would be left to the factory. Inspection might remain, as now, in the hands of a staff of medical experts, reporting to the Home Office, to the Ministry of Health, or to the local authority itself. Once industry appoints its own medical advisers the scope and standard of the work performed would soon exceed legal requirements. Much is made in the report of the Association, and rightly made, of the need for coöperation with school medical service, so that records of school years may be available when the young person starts on his life's work. Surely if the employer and that young person, through his parents, both require access to these records, the question of granting access could and would not be resisted. Any attempt to build upon this needed coöperation a reason for imposing the school medical service upon industry would do little to arouse interest among workers and employers.

THE ENTRY-APERTURE OF THE OVUM.

It is only within the present century that the older conception of the implantation of the ovum within the uterus has been replaced by the present-day description, which makes it attain its position by a process of destruction of the superficial part of the stratum compactum of the decidua. The earlier view postulated the well-known reflected, basal, and "true" layers of the mucosa, and the later belief replaces these with a "capsular" for the "reflexa" and a "parietalis" for the "vera." An aperture of entry, through which the ovum comes into the implantation cavity in the decidua, is, then, a necessity of the process, and is in fact well known to all who are acquainted with the literature on the subject. Not many human embryologists, however, have ever had the chance of studying this in actual specimens, and many are only acquainted with what is said by some to be the site of its former position, the "scar" of Reichert. But those who are able to examine the site shortly after the opening has closed will find it occluded by a fibrinous plug, which does not seem to have the leucocyte infiltration pointing to decidual origin. This would seem to be explained by a new description of the immediate closing of the aperture, given by Prof. T. H. Bryce in the very important and highly interesting lectures on Early Human Ova, delivered by him at King's College last month. He showed reason for believing that the aperture is closed at first directly by the trophoblast itself, this being modified later, presumably. In one of the sections he showed on the screen the outer layer was definitely projecting from the opening. This observation is of interest not only as providing for early closure while the ovum is enlarging, and accounting for the state already mentioned as existing a short time afterwards, but also as having some bearing on the question of the condition of the uterine cavity. Moreover, it may have some pathological connexions which will call for elucidation in the future.

THE THERAPEUTIC VALUE OF CINCHONINE.

Sir David Prain, in his Chadwick lecture, reported in THE LANCET of June 7th, remarked that, in view of the complaints of a world shortage of quinine, it must not be decided without consideration that the other alkaloids of cinchona bark are of no value. When this question comes up for settlement attention will have to be paid to a report on this subject recently published by Dr. Wilhelm Cordes,[1] working in the Tropical Medicine School at Hamburg. The author notes that cinchonine, following on the recommendation of Rogers,[2] Acton,[3] and others, is widely praised in Italy as an efficient substitute for quinine. To decide this question for the Hamburg cases he treated 16 early cases of first attacks of tropical (malignant) malaria, giving them all the usual treatment, except that, for each gramme of quinine in the routine, he substituted 1·1 g. of cinchonine alkaloid, the equivalent of 1·5 g. of cinchonine hydrochloride. The alkaloid is tasteless and easy to take, and it was absorbed and excreted in the urine as quickly as quinine, but it proved more ready to cause gastric uneasiness and vomiting. With this treatment, seven of the patients were at once cured, just as he would have expected to happen with quinine. The other nine lost their first attack of fever much as if they had been treated with quinine, but relapses were more frequent, and to secure their complete recovery quinine had to be given to them at last. He found, too, by study of blood films, that *P. falciparum* was less influenced by cinchonine than by quinine, for with it the ring-forms persisted longer in the blood, and reappeared more quickly when it was intermitted. Dr. Cordes concludes that cinchonine is less effective than quinine in the treatment of malignant malaria, although, like other observers, he found it could cure benign tertian, which, he remarks, is relieved by smaller doses of quinine, and even by arsenical preparations which have slight or no influence on the malignant form. On this evidence he has decided definitely that cinchonine cannot fully take the place of quinine. It might prove useful in places where *falciparum* infection does not occur.

SEX-INCIDENCE OF CAUSES OF DEATH.

SOME of the differences in the death-rate of males and females from individual diseases are both puzzling and suggestive. From their effect on the total death-rate the most important of these are tuberculosis, cancer, and syphilis. The crude annual death-rate from phthisis in England and Wales in the year 1922 was 31 per cent. higher in males than in females; while the death-rate from cancer was 11 per cent. higher in females than in males. Such death-rates evidently need further analysis to be satisfactory. In this country tuberculosis of the alimentary tract is slightly higher in males, but in the United States it is stated, in a recent statistical bulletin of the Metropolitan Life Insurance Company of New York, to kill more women than men. The cancer death-rate especially needs subdivision. Thus in 1922 the death-rate from cancer of the buccal cavity was more than seven times as great in men as in women; cancers of the pharynx, œsophagus, stomach, and liver were 28 per cent. more fatal in men than in women; but as cancer of the female genital organs and breasts caused over 25 per cent. of the total female cancer mortality, these more than accounted for the excess of female over male mortality from cancer. Evidently the local incidence of cancer in the two sexes points the way to further investigation into the exciting causes of malignant disease and to the possible adoption of preventive measures. The greater amount of syphilis in males than in females has much social significance. It points to the fact that extra-marital relations are the chief source of this disease; and that notwithstanding the terrible amount of syphilis imported by men into married life, this does not suffice to cause as much mischief as is produced by irregular sexual congress. The figures for general paralysis of the insane confirm this conclusion, the death-rate from this disease being five times as great in men as in women. In the bulletin referred to above, a number of illustrations of sex differences in the incidence of disease are given. The higher death-rate from whooping-cough in girls is well known, and the heavier incidence of all forms of goitre on women appears to be well established. In this country diabetes mellitus is slightly more fatal in women than in men; but in America the reverse appears to be the rule, a difference which may be explicable by the fact that men are more often examined for life insurance than women, and thus in women the disease goes oftener undetected than in men. Pernicious anæmia again is stated to be more common in males in America; in this country, according to official figures, the death-rate is more than 13 per cent. higher in women than in men.

THE FOOD-POISONING INCIDENT AT WEMBLEY.

SOME anxiety has been felt in regard to the recent outbreak of acute gastro-enteritis among visitors to the British Empire Exhibition at Wembley, and Major-General S. Guise-Moores, late R.A.M.C., director of medical services at the Exhibition, has been good enough to furnish us with the following notes.

"Eighty-seven cases of intestinal disturbance accompanied by vomiting, diarrhœa, abdominal pain, and constitutional symptoms, varying in severity, were admitted to the main ambulance station between the hours of 1 and 8 P.M. on June 9th last. The first symptoms supervened from one to three hours after partaking the 'mid-day' meal. The particular causative agent was the veal and ham pie, which was eaten by all the patients without exception. The clinical and symptomatic evidence points to a constitutional disorder due to the absorption of a toxin or toxins present in that food before it was consumed, and was not due to a bacterial infection of the food with subsequent multiplication in the intestine. The majority of the cases admitted to the main ambulance station were sent to their homes by car the same evening. Those that lived at too great a distance from the Exhibition, nine in number, were despatched by motor ambulance to the Willesden General Hospital that night, and discharged the next day. The 'pies' were withdrawn from the restaurants in their entirety very soon after the first cases were seen at the ambulance station. Samples of the pies have been sent for bacteriological investigation and report. Separate investigations are being carried out by the Exhibition authorities, the Ministry of Health, and the caterers concerned. The Ministry of Health has interested itself in the matter and sent Dr. Hancock to interview the D.M.S. of the Exhibition."

General Guise-Moores concludes: "It is considered that local conditions played no part in the causation of this outbreak, but that it possibly lies with factors which at present are difficult to control."

SMOKE ABATEMENT AT NOTTINGHAM.

THE experiment described in the *Municipal Journal* of June 6th, which is about to be made by the Nottingham Corporation in order to abolish smoke, should prove of great interest. It has been realised for some years that the partial coking of coal at a temperature below that used in ordinary gas-works was one of the means which might help towards the solution of the smoke problem, providing as it does a smokeless fuel suitable for domestic use as well as a rich gas and valuable by-products. The difficulty in the past has been to find a commercially practicable method, since the cost as well as the quality of the fuel produced is one of the governing factors. A market for by-products is also essential for the commercial success of such an undertaking. The industry of lace-making, which is special to Nottingham, calls for a very clean air, and this doubtless had some influence in deciding the corporation. The conditions under which 1000 tons of coal per day can be treated at a colliery in the vicinity of the city which provides a market for the solid fuel, gas, and by-products produced should give the experiment every chance of success. We must join issue, however, with our contemporary when it is stated, with reference to smoke, that "municipal authorities are unable to accomplish any improvement worth speaking about." Measurements show that in London and Glasgow there has been a great and steady improvement in the direction of smoke reduction of recent years. There are, unfortunately, no measurements of smoke pollution available for Nottingham, which may, therefore, call itself a "clean city" without fear of contradiction. We would urge the corporation to obtain such measurements without delay for comparison with future conditions which will result from their experiment. Such figures would be of real value both to Nottingham and to the country generally as indicating the degree of success attained.

NEW MENTAL HOSPITAL ACCOMMODATION.

LACK of hospital accommodation for mental disease is acute and almost universal: so long has it prevailed, indeed, that the communal conscience is in danger of becoming hardened. Two bright spots are on the picture. One is the opening, just as we go to press, by the Minister of Health of the West Park Mental Hospital, the fifth institution to be provided by the London County Council on the Horton estate at Epsom. This hospital, when completed, will accommodate 2096 patients (1128 males and 968 females), and includes an admission block, villas for convalescent patients, special wards for the treatment of tuberculosis and dysentery. A chapel, infirmary, and acute wards for female patients will not be ready for occupation until the end of 1925. The other bright spot is the decision of the governing body of the St. Andrew's Hospital for Mental Diseases at Northampton to erect a special hospital for the reception and treatment of early cases of mental disorder. The foundation-stone is to be laid on June 27th, and judging by the plans contained in a circular accompanying an invitation to this ceremony, a very careful study has been made of arrangements elsewhere for the separation of the recently admitted from the chronic insane. Visits were paid by the subcommittee entrusted with this duty to several psychiatric clinics on the Continent, and to an English spa for the purpose of studying hydrotherapy, which is to be an important feature of the treatment employed in the new hospital. Accommodation will be provided for 16 patients of each sex. The equipment of this hospital will evidently be more varied and extensive than that of any other institution of its size in this country. Ten varieties of hydrotherapy are provided for, bacteriological and chemical laboratories, rooms for X-ray and electrical treatment, a dentists' room, and various other facilities for special treatment. The authorities of the St. Andrew's Hospital are to be congratulated on tackling with such vigour an urgent problem which is beset with difficulties. Not only will the expense of building this hospital be considerable, but the expense of maintaining it in full working order will probably be equivalent to a capital expenditure many times greater than the cost of building. A numerous staff will be required in order to administer its special departments with due efficiency, although in regard to laboratory investigations it will be open to the hospital to avail itself of the Joint Board of Research for Mental Disease when material can be sent to Hollymoor for investigation. A précis of the year's research work there appears on p. 1286. We have no information at present as to the arrangements in view for staffing St. Andrew's Hospital, or as to the proportion of the cost of upkeep which is to be borne by the patients. It is observed that the hospital "can, if necessary, be extended," and one may safely predict that such extension will be found desirable. The facilities for treatment are arranged on such a scale as to be capable of dealing with a much larger number of patients than can be accommodated in the hospital as planned at present. The success of this venture will be watched with keen interest by mental hospital authorities throughout the country. In the millennium of lunacy administration such a reception hospital will be considered a sine qua non by every large institution, and in the meantime it is probable that wherever extended accommodation is required the extension will take some such form as this.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXVI.

THE TREATMENT OF ACUTE GONORRHŒA IN THE FEMALE.

GONORRHŒA in the female may start acutely or begin so insidiously that it is scarcely noticed at first by the patient. Pregnant women, and those who have borne several children, are so accustomed to transient attacks of frequency of micturition and leucorrhœa that, in cases of the disease commencing mildly, the condition may not be recognised until complications ensue. As a rule, the younger the patient the more acute the onset. In a case suspected to be gonococcal, the patient should be instructed (1) not to douche for 24 hours before examination, (2) not to empty the bladder for at least three hours before being seen. Neglect to observe these precautions may completely invalidate any opinion expressed as to the absence of the gonococcus in mild cases.

Symptoms.

In private practice there may be some difficulty in getting patients, especially recently married women, to submit to a complete examination, particularly when smears are taken for slides and culture. But the importance of checking the condition at the onset is so great that every effort should be made to establish the diagnosis definitely. The word "inflammation" covers a multitude of sins, and gonorrhœa need not be mentioned unless one is compelled to do so.

The four main signs in the adult are vulvitis, bartholinitis, urethritis, and endocervicitis.

Vulvitis in the adult is usually secondary to a bartholinitis, urethritis, or endocervicitis. The mucous membrane of the vulva in the adult, unlike that in the child, is not readily attacked by the gonococcus until secondary infections by staphylococci or the *Bacillus coli* are superadded to the previous gonococcal trouble. Vulvitis in the adult, therefore, usually occurs in neglected cases, debilitated patients, and women of weak mentality. It yields readily to medicated baths when the conditions causing it are treated adequately.

Bartholinitis.—Inflammation of Bartholin's gland and duct is generally gonococcal. It is unilateral in 60 per cent. of cases. If the duct is inflamed, the orifice on the inner surface of the labium minus, opposite the vestibule, will show as a yellow punctum surrounded by an almond-shaped inflamed area—the "gonococcal macule." The gland is not palpable in health. If it can be felt in the lower third of the labium majus it may be assumed to be enlarged. The condition is usually associated with a vulvitis, and in the early stages can be aborted readily by two injections of 1 c.cm. manganese butyrate (1 per cent.) given, at five days' interval, intramuscularly into alternate buttocks. This drug acts like a charm in the primary inflammatory stage; the vulva clears up, the small central abscess comes to the surface and discharges, the septic condition quickly subsides. If, however, there is already an abscess the size of a walnut, associated with a much swollen labium, the ideal treatment is a T-shaped incision, complete removal of the gland, and gauze packing of the cavity to ensure healing from the bottom.

Urethritis.—This is present in 80 per cent. of cases, but the subjective symptoms are often so mild that only about 5 per cent. of women give a history of pain and frequency. Attention, therefore, is often concentrated on the cervix alone, with the result that, when this is cured, the patient is often pronounced free whilst still dangerously contagious. When urethritis is present, examination will show pus (either directly or after massaging the urethra from the vagina), or inflammatory thickening, induration, or pain on pressure. In addition, the presence of the gonococcus can often be demonstrated in the paraurethral or suburethral crypts. Skene's ducts, two small cul-de-sacs opening on either side or just inside the urethra, are constant sites of infection. Treatment consists in irrigating the urethra with permanganate of potash, 1/10,000, by means of a two-way cannula. Or, instead, one may use a female urethral syringe with a fenestrated nozzle, and inject 1 per cent. protargol in glycerine daily in acute cases, or 10 per cent. protargol in glycerine weekly in chronic cases. As a rule, the female urethra is very tolerant of topical treatment; but occasionally, especially if acute cystitis is present, local treatment cannot be carried out, and then one has to rely on medicated sitz-baths and alkaline treatment for the cystitis. There are a few Littre's glands in the female urethra, and soft infiltrations and suburethral abscesses form occasionally, with subsequent risk of stricture. For these, massage from the vagina on a straight metal sound—22–24–26 French—followed by irrigation, is the treatment indicated. Skene's ducts, and any paraurethral crypts infected, should be obliterated by probes tipped with fused silver nitrate or the thermo-cautery.

Acute endocervicitis is, of course, the cardinal lesion in the adult female. It is also the most difficult to cure; for here we are dealing with a columnar epithelium having many crypts, pouring out an alkaline secretion—in every way the most favourable possible nidus for the gonococcus. The main symptom is a profuse, persistent "vaginal discharge." The carunculæ myrtiformes are generally inflamed, and so examination is painful or impossible in the very early stages. As soon, however, as a speculum can be passed it will be found that the vagina itself is little implicated, but that the cervix is enlarged and tender, the canal is friable, bleeds easily, and is pouring out a thickish yellow discharge over the somewhat eroded posterior lip of the os. Treatment consists in douching the vagina twice daily to remove the discharge, and treating the cervical canal with topical applications as soon as a speculum can be introduced without undue pain. Many combinations of drugs have been tried for this condition. The two methods described below have proved satisfactory.

Hypochlorous Acid Treatment.

This consists in using any of the various chlorine preparations—e.g., Dakin's fluid in the form of chloramine-T, or one of the hypertonic solutions of sod. hypochlorite now on the market, as a douche twice daily, and also as a topical application to the endocervix once a day. The strength of the douche is 1/1000 to 1/500. Douches only are used at first until it is possible to pass a speculum. As soon as this period arrives the instrument is inserted daily if possible—certainly not less than twice weekly—and the fornices and cervix swabbed clear, by means of wool on holders, of the veil of pus and mucus obscuring the field of operation. The cervical canal is next freed from discharge and mucus by Playfair probes tipped with cotton-wool, either dry or soaked in peroxide of hydrogen. When the canal is clear the chlorine solution in a strength of 10 per cent. is similarly applied up to the internal os; and the vagina finally swabbed out with wool on a holder as the speculum is being withdrawn. At the same sitting any inflammatory foci around the urethral or vaginal orifices are also treated. Should there be frequency of micturition a bladder irrigation of 1/1000 is used. These manipulations, combined with a daily sitz-bath, will cause rapid improvement in about ten days; and one can then lengthen the time between topical treatments according to the symptoms. Another drug which can be used in the same manner and in the same strengths is acriflavine.

An equally successful method is the manganese-contramine treatment introduced by McDonagh. The patient is put to bed and an intramuscular injection of 1 c.cm. manganese butyrate is given, followed by a 1·5 c.cm. injection on the fifth day. This drug reduces the acutely painful stage of profuse discharge to a few days; and douches of pot. permanganate, 1/4000, are then given for the next three or four days. The patient is then started on a course of 30 contramine pessaries. These are inserted nightly against the cervix, and held in position by a gauze tampon. The tampon is removed in the morning, when another permanganate douche is given. At the end of the course smears are taken, and if still positive the contramine is repeated. Markedly good results have been obtained by this treatment. For subacute cases, when the patient is seen for the first time after the condition has lasted some months, it will be found that 10 per cent. protargol in glycerine, twice weekly, is an excellent topical application. Each treatment by this drug should be completed by inserting a gauze tampon, soaked in the same medicament, packed round the cervix. There it remains for 12 hours, when it is withdrawn by means of its string, and a douche of 1 per cent. lactic acid given. Normally, the vagina is acid, its acidity being due probably to the *Bacillus acidi lactici*. The strength of the acidity is 0·9 per cent., and this is inimical to most bacteria. Lactic acid in 1 per cent. solution is therefore recommended as a vaginal douche in all chronic conditions because it is the nearest approach to Nature's method.

The Rationale of Douching.

Douching was at one time the only treatment used in combating this disease; and it is still too frequently relied upon in general practice. Many of the drugs used were not only physiologically unsound, but positively detrimental. The so-called mucous membrane of the vagina is not a real mucous membrane. It is a modified skin with a surface composed of squamous epithelium. There are no glands in it, and it is therefore extremely resistant to organisms. Substances like corrosive sublimate, silver nitrate, picric acid, alum, zinc, any of the coal-tar preparations which precipitate albumin, largely destroy the normal protective mechanism by producing a desquamation of the surface epithelium, thus allowing the gonococcus to penetrate much more easily than it otherwise could. A great deal of the "granular vaginitis," which used to be so common years ago, was undoubtedly due to the over-use of powerful caustic douches such as corrosive sublimate; and the reason why we do not see this condition anything like so frequently to-day is because a much more sensible view is now taken of the value of antiseptics as curative agents in themselves. In gonococcal disease the practice of douching with these powerful antiseptics originated from the erroneous assumption that the vagina was infected with the gonococcus, and that any cervical discharge also present could be cured by the vaginal douches used. It is unfortunate from the standpoint of rational treatment that the mucous membrane of the vagina is comparatively insensitive, and so these caustics can be used with impunity—caustics which simply erode away the normal protective layers of the epithelium and so allow infective organisms to penetrate. Powerful antiseptics are not required in the vagina; they do not affect the cervix. Primary gonococcal vaginitis, except in children and in extreme old age, is very rare. Douching the vagina, therefore, should be largely for the mechanical purpose of getting rid of discharge; and a mild acid preparation, such as 1 per cent. lactic, or boric, or any of the preparations such as Dakin's fluid, which does not precipitate albumin, should be used, unless, of course, an infective vaginitis is present.

J. JOHNSTON ABRAHAM, C.B.E., D.S.O., F.R.C.S.,
Surgeon, the London Lock Hospitals.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The annual distribution of prizes will take place in the Governors' Hall on Friday, June 27th, at 3.30 P.M., when the Duke of Connaught will preside. There will be tea and music on the terrace.

Public Health Services.

SCHOOL MEDICAL SERVICE.

Sheffield.

OF a school roll of close on 84,000, nearly 30,000 children were examined during routine inspection and 19·6 per cent. of the elementary school population were referred for treatment, 12·5 per cent. of these being kept for further observation and 94·8 receiving treatment. The medical staff consists of the school medical officer with seven full-time and five part-time assistants, a chief school nurse with 25 full-time assistant nurses, three dental attendants, and a dispenser. The most recent council schools contain special rooms for medical inspection, and in four schools branch clinics have been established. An extra evening clinic for the treatment of toothache is held three times a week, and its success is evidenced by an average attendance of 44 children each evening. Although verminous conditions have decreased considerably, it is a great pity that attention to bodily cleanliness has diminished. Dr. T. Chetwood reasonably attributes this to closing the shower baths in four of the largest schools. The popularity of the school clinics is demonstrated by the total attendances, which numbered 238,236, an appreciable increase on the figures for 1908, when 34 per cent. of those requiring it obtained treatment. A study of the steady rise in the number of those obtaining treatment in successive years leads inevitably to the conclusion that the popularity of the clinic as well as increased facilities for treatment are the responsible factors. Dr. Chetwood points out that there is obviously a limit which should be set high beyond which it is impossible to go, some children naturally leaving school before treatment is completed and others, a smaller number, being lost sight of owing to removals or other causes, and a trifling percentage who refuse treatment.

The number of cases treated at the X ray and skin clinic totalled 5910 for the year. The incidence of ringworm has diminished considerably, the number of children presenting generalised infection being considerably smaller. Parents now present themselves asking for X ray treatment for the children. The number of scabies cases, too, has dwindled to less than 200, and there has also disappeared the large number of severe impetiginous infections so common up to the end of 1922. Whiteley Wood and Springvale House continue to show good results, and plans are being made to increase the accommodation in both those open-air schools.

Dr. Percival J. Hay has made an elaborate investigation into the ability of the myopic child to maintain a working distance of 30 cm. when wearing glasses. Fifty-three children were examined individually under correction, and the farthest distance at which the finest Jaeger types the child was capable of seeing was noted. Tables are given showing the near vision at 30 cm. and at the distance preferred by the child. "It is natural that all these children would select the distance which would give them best vision and to ask them to keep their work at a longer distance seems to be futile. In any case, it would seem to be wise to find out first what a child's vision is at 30 cm. before we enjoin upon him to keep at that distance." But is Dr. Hay not mistaking the purpose of the sight-saving schools which is to eliminate near work entirely from the curriculum? In a properly conducted myope school no child should be asked to work as close as 30 cm., the kinæsthetic sense is trained as far as possible, and all fine work is taboo. And, in any case, by finer correction many of these children could, no doubt, have had their optimum working distance adjusted to 30 cm. Physical instruction is being dealt with in Sheffield on a thoroughly scientific basis, and in spite of economic restrictions the needs of the Sheffield school children in this direction are being well looked after.

Bootle.

There has been an increase in the amount of work done in all branches of the medical service during the year and the dental work has been extended by the appointment of a second part-time dentist. Out of 3213 children referred for dental treatment 2481 were dealt with. The number of elementary school children examined under the code groups was 4134, and of these 38 per cent. required treatment. Special examinations and inspections amounted to over 9000. Eleven selected cases of discharging ears were treated by zinc ionisation. Four were cured after from 4 to 11 administrations, three ceased attendance, and seven were carried into the new year. The orthopædic scheme with the remedial exercises clinic is working well. 332 cases were treated during the year and 4442 attendances were made. Mouth-breathers accounted for 129 of these, and infantile paralysis for 52.

Shrewsbury.

Shrewsbury has an average school attendance of 3715, and of these 1248 were medically examined; 3·8 per cent. required treatment, and altogether 1148 children made 6371 attendances at the school clinic. Ringworm of the scalp accounted for 183, ringworm of the body for 152, impetigo for 523, and 679 attended for verminous conditions; 4755 attendances are classed as "miscellaneous." Dental treatment was given to 158 children. An effort is being made to educate the children in elementary hygiene, and the result of this ought shortly to make itself evident in the schools. Dr. H. E. Smith deplores the verminous condition of the children, and the prevalence of impetigo which accompanies personal uncleanliness. He attributes the state of things largely to laziness on the part of both parents and children. The teacher can do a great deal in this direction, and the introduction of lessons on personal hygiene if made practical enough ought to stimulate a consciousness of uncleanliness in the children. But precept without practice is worthless.

Bedford.

The work of "following up" has been extended in this county by arrangement with the Bedfordshire Nursing Association for the district nurse to be present at medical inspection, and later on to visit the homes for the purpose of ascertaining whether treatment has been obtained, and if not, to advise and assist parents in obtaining it. A fee of 7*s.* 6*d.* and a capitation grant of 6*d.* per child medically examined is paid for the nurse's attendance. The teachers in this way have the help and coöperation of the district nurse, and although dealing with verminous conditions may cause difficulty at first, the utilisation of the district nurse in this connexion ought to be a distinct advantage to the county. More attention has been paid to paving, draining, and re-tarring playgrounds this year, and the water-carriage system has been introduced into two schools. The number of children examined in the routine group was 5483, and 69·3 per cent. of the parents were present. Dr. R. T. Herdman emphasises the importance of dry shoes and stockings for children coming from a distance. He says that parents, not teachers, make a difficulty of this matter, and steps are being taken to educate parents.

Hartlepool.

After the resignation of Dr. G. A. Jubb in April of last year, the post of school medical officer was vacant until Dr. W. McKendrick took over the work after the summer holidays, with the result that much leeway had to be overtaken, as no routine inspections were undertaken until September. Owing to unemployment, many children were compelled to go poorly clad and bootless to school, and funds were raised to provide boots and stockings for these children. There were 14 cases of malnutrition found, none of which required actual treatment. Parents attend the examinations well, and the school clinic is well patronised. Dental treatment is going ahead, and a clinic is shortly to be opened in Hartlepool, so that the long journey to West Hartlepool, hitherto necessary, will be avoided.

Gillingham.

Dr. W. A. Muir, senior medical officer, states that since the last report a considerable improvement has been effected in the general cleanliness of school sanitary arrangements. Sanitary inspectors now inspect at frequent intervals. Much still remains to be done; in one school there is one hand-basin to 200 boys, and Gillingham is by no means alone in such a penury. Now that so much has been accomplished in remedial provision, it is time to concentrate on preventive measures. Cleanliness is the most important of these—cleanliness of schools and scholars—and here, as Dr. Muir states, example is better than precept. "A few practical examples of sound hygiene are infinitely more valuable than innumerable lessons on health." In Gillingham if only one nit is found on the hair the child is classified as verminous, with the result that of the 15,763 children examined at the nurses' inspections, 9·6 per cent. were found verminous. Sacker combs can be hired by the parents at a charge of 1*d.* The Danish method of treatment for scabies was adopted during the latter half of the year, and in most cases resulted in a cure after a single application. Among 2086 children medically examined, only four cases of rickets were found.

At *Bournemouth* the school medical officer, Dr. W. V. T. Styles, impresses upon parents the advantages they have in living near the sea. They are advised gradually to tan the bodies of their children by exposing them by stages to the sun's rays on the beach in the summer months. Systematic treatment for pre-tuberculous children by sun-baths is carried out daily with excellent results.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 7TH, 1924.

Notifications.—The following cases of infectious diseases were notified during the week—namely, small-pox, 69; scarlet fever, 1344; diphtheria, 657 (as against 788 of the previous week); enteric fever, 82; pneumonia, 742 (as against 900 of the previous week); puerperal fever, 43; cerebro-spinal fever, 3 (as against 14 of the previous week); acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 179 (as against 251 of the previous week); continued fever, 1; dysentery, 10; ophthalmia neonatorum, 139. There were no cases of cholera, plague, typhus fever, or trench fever notified during the week. Of the 69 cases of small-pox, 27 were notified from the county of Derby (Derby 10, Chesterfield 11), and 13 from Northumberland (Ashington). Of the cases of encephalitis lethargica, 22 were notified from the County of London, 11 from the county of Durham, 4 from Bristol, 26 from the county of Lancaster (Liverpool 10), Northumberland 11 (Newcastle-upon-Tyne 6, Wallsend 4), Yorks, East Riding, 9 (Hull 8), Yorks, West Riding, 22 (Sheffield 10, Halifax 2, Bradford 2 Wakefield 2, Wetherby 2), and Monmouth 3.

Deaths.—In the aggregate of great towns the deaths from influenza fell further from 52 to 46. There were in London 8 deaths from diphtheria, 6 only from measles.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Cmdr. J. Thornhill is placed on Retd. List, with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Temp. Maj. S. L. Hinde relinquishes his commission and retains the rank of Maj.

ARMY RESERVE OF OFFICERS.

Lt.-Col. F. E. Gunter, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Capt. H. A. Harbison ceases to belong to the Res. of Off. on account of physical unfitness.

ROYAL AIR FORCE.

The undermentioned are granted short service commissions as Flying Officers: A. Dickson and A. A. Townsend.

RESERVE OF AIR FORCE OFFICERS.

Flying Officer on probation A. Dickson resigns his commission.

INDIAN MEDICAL SERVICE.

Col. R. Heard, K.H.S., to be Maj.-Gen.

Lt.-Col. E. F. E. Baines to be Col.

HONORARY PHYSICIANS AND HONORARY SURGEONS TO THE KING.

To be Honorary Physicians: Col. H. J. K. Bamfield, I.M.S., vice Maj.-Gen. Sir Courtenay C. Manifold, I.M.S. retd.; Col. J. H. McDonald, I.M.S., vice Maj.-Gen. C. H. Bowle-Evans, I.M.S. retd.; Lt. Col. A. Hooton, I.M.S., vice Maj.-Gen. W. E. Jennings, I.M.S. retd.

To be Honorary Surgeons: Col. F. Wall, I.M.S., vice Col. W. G. Pridmore, I.M.S. retd.; Col. P. Dee, I.M.S., vice Col. H. A. Smith, I.M.S. retd.: Maj.-Gen. T. H. Symons, I.M.S., vice Maj.-Gen. Sir Gerald G. Giffard, I.M.S. retd.

DEATHS IN THE SERVICES.

Major Valentine Good Johnson, R.A.M.C., who died at Sidmouth on June 14th, qualified from St. Mary's Hospital with the Conjoint Diploma in 1905, and had been clinical assistant at the London Lock Hospital and house physician at the Bethlem Royal Hospital. He joined the Army as Lieutenant R.A.M.C. in 1906, reached the rank of Captain in 1909, and that of Major in 1918. He was only 45 years of age, and leaves a wife and many friends to mourn their loss.

Special Articles.

VENEREAL DISEASE IN BELGIUM.

A Successful Campaign.

A PAPER by Dr. L. Bernard,[1] of Brussels, on the work of his dispensary shows that gonorrhœa is on the wane, and syphilis is rapidly disappearing as the result of the concerted measures recently taken against them. It is strange to read of a chancre as a rarity, as a lesion which teachers show to students with the words: "Mark it well, for you may never see it again." During the five years the first State dispensary has existed in Brussels, records have been compiled of 3319 cases representing 57,674 attendances. Of these 3319 cases, 1126 were due to syphilis, 1348 to gonorrhœa, 15 to chancroid, and 1 to inguinal lympho-granuloma. The remaining 829 persons attended the dispensary because they wrongly feared they were suffering from venereal disease. Gonorrhœa being much more prevalent than syphilis, it is remarkable that the numbers of these two diseases treated at the dispensary were approximately equal. Evidently many cases of gonorrhœa never come to a dispensary for skilled treatment, and this is one reason why the incidence of gonorrhœa is not declining as rapidly as that of syphilis. Another curious difference between syphilis and gonorrhœa was the relative numbers of the two sexes: apart from the cases in children, there were 729 male and 376 female cases of syphilis, and 996 male and only 348 female cases of gonorrhœa. These figures suggest that gonorrhœa in the female is comparatively often overlooked.

The Importance of Specialist Diagnosis and Treatment.

Dr. Bernard publishes statistics, culled from official notifications, showing the numerical differences in the diagnoses of syphilis and chancroid in fully equipped dispensaries managed by specialists on the one hand, and under the conditions of a private consultation on the other. In 1921 the ratio of chancroid to syphilis was 0·74 per cent. at the dispensaries and 5·15 per cent. at private consultations. As the same great differences were observed in 1920 and 1919, they were evidently not accidental, and it is probable that, for want of sufficient knowledge and laboratory equipment, physicians are apt to mistake many cases of syphilis for chancroid. It may not matter much to the community if a case of chancroid is taken for one of syphilis, but the opposite mistake may have serious consequences for both the patient and the community.

The Disappearing Chancre.

In 1920 there were as many as 108 cases of primary chancre seen at the dispensary. In 1921 this figure had fallen to 38, and in 1922 to 12. In 1923 there were 16 such cases. In the same period there was a corresponding fall in the number of cases of secondary syphilis, from 102 in 1920 to 11 in 1923. But the number of cases of syphilis, showing no apparent lesion, rose from 74 in 1920 to 147 in 1923. This decline of the proportion of primary cases to all the cases of syphilis from 35·64 per cent. in 1920 to 8·42 per cent. in 1923 is an amazing achievement. Dr. Bernard publishes a chart showing the connexion between various administrative Acts and the incidence of syphilis and gonorrhœa. Thus, in the second quarter of 1920, the Belgian Government provided every doctor in the country with a free supply of specific arsenical preparations, and already in the same quarter the chart shows an abrupt fall in the number of cases of primary syphilis. The same chart brings out the interesting fact that propaganda movements tend to coincide with a great increase in the number of persons coming to the dispensaries for examination, although they are not suffering from venereal disease.

Sources of Infection in Male Cases of Venereal Disease.

Dr. Bernard's classification of the sources of infection shows some surprising observations. Not a single case could be traced to the "official" prostitutes who number about 300 in Brussels, but over 56 per cent. of all the new cases could be traced to clandestine prostitutes. Another 24 per cent. could be traced to "femmes de passage"—a somewhat ill-defined class which played an important part in the dissemination of venereal disease after the armistice when the home-coming, demobilised soldier was received with more warmth than discretion by his patriotic countrywomen. Only about 16 per cent. of the new infections could be traced to mistresses, and only between 2 and 3 per cent. to wives.

Importance of Examining the Cerebro-spinal Fluid in Syphilis.

The following statistics show how unsafe it is to rely solely on a negative serological examination in deciding whether or not syphilis has been cured. In 1923 there were 109 cases of syphilis in which the Bordet-Gengou reaction was negative in the blood and there had been no clinical signs of activity for six months to two years. But only in 30 of these cases was the reaction negative in the cerebro-spinal fluid—in other words, the cerebro-spinal fluid showed signs of persistent disease in more than 71 per cent. of the 109 sero-negative cases. In view of these findings Dr. Bernard insists that a syphilitic patient who contemplates matrimony or departure to the Belgian colonies should have his cerebro-spinal fluid as well as his blood tested for syphilis before conclusions are drawn as to his fitness for either step.

Arsenical or Bismuth Compounds in Syphilis.

In 805 cases arsenobenzene and in 248 cases bismuth preparations were given. Signs of arsenical poisoning occurred in as great a proportion as 18 per cent., but no fatalities had to be recorded, although in nine cases the sequels, such as exfoliative erythrodermia, were serious. On one occasion a supply of arsenobenzene appeared to be particularly toxic, and this consignment was therefore withdrawn by the manufacturers. The number of cases of arsenical poisoning was greatest during 1919, 1920, and 1921, and it would seem that the improvement observed in this respect during 1922 and 1923 must be traced to the conditions under which arsenobenzene is manufactured. The monopoly enjoyed by two manufacturing firms no longer exists, but the many manufacturers now turning out arsenobenzene and similar antisyphilitic preparations have since 1922 been under Government control. Dr. Bernard's experience with bismuth is most promising. Among his 248 cases treated with bismuth there were only 19 in which stomatitis developed. No case of nephritis was observed, and there were only two doubtful cases of jaundice. Bismuth would seem to be more effective than the arsenic preparations in neuro-syphilis, and there can be no doubt that it is far safer to administer. Practically the only risk associated with it is that of stomatitis, and this can, to a great extent, be avoided by careful hygiene of the mouth. The discovery of bismuth is most opportune now that cases of arseno-resistant syphilis are becoming common. Dr. Bernard's opinion of the value of bismuth is so high that he considers it desirable for bismuth to be provided by his Government free of charge.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Feeding of Unconscious Persons.

AT a recent meeting of the Vienna Medical Society Dr. Flesch demonstrated his method of feeding persons who are functionally unable to swallow. He refrains from introducing a nasal tube, especially in cases of meningitis, cerebral hæmorrhage, general sepsis, or other conditions of partial or complete unconsciousness. In these persons either a diminished tonus of the jaws and the muscular apparatus of deglutition, with consequent dropping of the lower jaw, or extreme dryness of the mouth or pain, renders swallowing impossible. If sensation is completely absent the reflexes disappear and an endeavour must be made to feed the patient per rectum. Dr. Flesch's method of feeding is as follows. The patient is placed flat on his back and a few grammes (3–5) of lukewarm milk, coffee, soup, &c., are instilled, by means of a dropper or a small spoon, into the nostrils. The liquid makes its way along the vertical floor of the lower nasal passage, drops on the inclined plane of the posterior pharyngeal wall—at an angle of about 110°—and rapidly flows directly into the uppermost part of the œsophagus, where the constrictor pharyngis inferior presses it into the œsophagus. This happens without even touching the laryngeal region, so that there is no danger of aspiration. The method is applicable even when the corneal reflex is absent, for it has been shown by X ray experiments, made with a barium emulsion, that this pharyngeal reflex seems to be the "ultimum moriens" of the act of deglutition. In order to prevent the desiccation of the mucous membrane of the mouth in patients with prolonged and intractable mouth-breathing in coma, unconsciousness, and high fever, Dr. Flesch has constructed a small apparatus which closes the lips but contains a valve, through which expiration only is possible. Thus the patient is forced to inspire through the nose, whilst the moistened expiratory air-blast can pass out through the mouth. The apparatus can be worn for a prolonged period without any harm to the lips.

Prof. Pirquet's Fiftieth Birthday.

The fiftieth birthday of Freiherr Clemens von Pirquet was celebrated recently by his numerous friends and pupils with unusual solemnity. In his clinic the professor was the recipient of congratulations from all sources on this occasion, and the learned societies of Austria, as well as the pediatric societies of Germany and other countries, sent delegates to the professor, expressing their good wishes and their esteem. A special meeting of the Austrian Society for Pediatrics was held on May 12th, in which Prof. Magerhofer, one of Pirquet's oldest pupils from the University of Zagrele (Yougoslavia), delivered an address on the biological value of Pirquet's investigations. It may be mentioned here that Prof. Pirquet was at one time director of the children's clinic at the Johns Hopkins University in Baltimore, and of a similar clinic in Breslau (Germany), before he was called upon to take over the Vienna University children's clinic at the early age of 37. His reputation is international; his reaction is now one of the fundamental principles in diagnosis of tuberculosis. This method was worked out by him when still a young assistant of Prof. Escherich in this city. The problems offered by the infectious diseases soon attracted his attention, and his investigations on allergy gave a solid base for the modern methods of therapy with protein bodies; together with Schick he studied the so-called serum disease and the process of immunisation by vaccination. One of the latest additions to modern therapeutics was the systematic control of nutrition by means of the Nem method—i.e., the nutritional value of foods calculated by the caloric value of 1 g. milk as unit. This method facilitated the systematic feeding of hundreds of thousands of starving children by the "Save the Children Fund" and "Famine Area Fund" of Great Britain and the United States at a minimal cost and with a maximum effect. The clinic where Pirquet has been working for the last 13 years has become the Mecca of doctors desiring knowledge of the important art of treating the ailments of childhood. Original research, excellent organisation, and independent ideas are the leading features of his work.

The Medical Profession and the Problem of Artificial Abortion.

As has been mentioned in a previous letter (vide THE LANCET, Jan. 12th) forensic authorities have taken a very energetic attitude in regard to artificial interruption of pregnancy, even when performed by medical men. In fact, the Supreme Court has recently inflicted severe penalties on several doctors who were charged with having induced abortion without absolute necessity. An order of this court went so far as to make it imperative for all persons coming professionally to a knowledge of an abortion to report the matter to the police. The medical profession has most vehemently protested against such an infringement of the existing law compelling the doctor to maintain professional secrecy. The medical council is supporting the profession in this struggle, and an organised campaign is being maintained in order to bring about a change of legislation in accordance with the requirements of modern views and the necessities of modern life. Whilst supporters of eugenics strongly advocate the widespread use of contraceptives and the instruction of the poorer classes in their use, another section, and by no means a minority section, of the profession favours rather a control of births by giving doctors or a committee of health officers discretionary powers to advise and produce abortion in the first three months of pregnancy. Recently a mass meeting of the profession, attended by about 40 per cent. of the doctors of Vienna, discussed this problem. While Prof. Tandler explained the necessity of birth control from the sociological standpoint—namely, to prevent an excess of offspring in poor families, leading to pauperism—Prof. Hammerschlag pointed out that in the case of deaf-mute or mentally diseased persons eugenic principles should be the guide in considering the advisability of children being born to them. Many other speakers regarded a diminishing birth-rate as a characteristic of all nations attaining a certain level of civilisation. It is inevitable, unless the economic conditions of a people become such that the new-born individual is sure to find its upbringing assured, and at present this is attained nowhere. The meeting passed a resolution which will be brought to the notice of all the authorities concerned and which sets forth that the present drop of the birth-rate is the direct outcome of the social and economic conditions now existing. It cannot be combated by law, but only by removing the underlying causes, and as long as these are effective contraceptive measures are more advisable than abortion, because the latter is always fraught with a certain degree of danger. The resolution further states that the meeting does not advocate free right to procure abortion unconditionally, but that it strongly favours a modification of the law in the light of medical and social contingencies.

THE Williams and Wilkins Company of Baltimore, U.S.A., announce the forthcoming of a book by Dr. John T. King, jun., of Baltimore, entitled Basal Metabolism, for the student and practitioner.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Local Government Bill.

THE anxiety of the medical profession of the Irish Free State as to the Pensions clauses of the Local Government Bill is not likely to be diminished by the speeches made by the Minister of Local Government in debate. If he is correctly reported (and the report is the same in more than one newspaper) he used the following words: "Medical officers at present carried on private practice as well as attending to their public duties, and notwithstanding this fact, they were allowed pensions. It was not considered desirable to continue that practice." If the words mean what they appear to mean, then it is only right to say that the Minister's wishes go far beyond what he has put in his Bill. In the Bill it is clearly laid down that part-time medical officers are pensionable. Some of the Minister's other contributions to the debate leave one uneasy as to his familiarity with problems of public health. The Bill provides for the appointment of whole-time medical officers of health in each county. Mr. Burke, in arguing for the necessity of this step, gave as one of his reasons that the county medical officer of health could act as medical inspector of school-children in his area. One need hardly say that under such conditions both the inspection of children and the public health work would be sterile. The profession and the public are fortunate in having in the Dail one who is so familiar with health problems as Sir James Craig, whose speeches in regard to the present Bill have been sound and constructive.

Inquiry into the Health Services of Ireland.

The first meeting of the Committee of Inquiry into the health services of the Irish Free State, appointed by the Minister of Finance, was held last week. The terms of reference are wide: (1) To inquire into and report on the advisability of the continued maintenance of the system of national health in its present form, and to make any recommendations which the committee consider proper in that connexion; (2) to consider whether it is desirable to institute a system of medical treatment on a contributary basis and, if so, to advise as to the form which such system should take; and (3) to examine into and report on the question whether the medical services at present assisted or maintained out of State or local funds can be improved as respects efficiency and economy and, if so, in what manner, due regard being had to any recommendations made under the preceding paragraph. Prof. W. Magennis is chairman of the committee; and the other members are Sir Joseph Glynn and Dr. W. J. Maguire, chairman and medical member respectively of the National Health Insurance Commission; Dr. Stephenson and Mr. Hurson, of the Ministry of Local Government; Mr. McElligott, of the Ministry of Finance; Mr. Kyd as Government actuary; Rev. Canon McHugh, and Dr. Robert J. Rowlette.

Public Medical Appointments and Competitive Examinations.

The practice of election of medical officers by local authorities throughout Ireland has often been the subject of criticism. At best the electors are likely to be swayed by ties of family and friendship, and at worst charges of bribery have been made. The Ministry of Local Government has just held a sworn inquiry into the circumstances surrounding a recent election of a medical officer in Co. Roscommon, in regard to which charges of bribery were openly made. It is refreshing, therefore, to find a local authority demanding a mode of appointment which would be free of all impurity. At a recent meeting of the Tipperary County Health Board (N.R.) a resolution was unanimously agreed to: "That all medical appointments of the County Health Board be made by competitive examination or selection; that the applicant who has been reported as possessing the highest professional qualifications and experience shall in all cases be appointed; that the Board of Health request the assistance of the Ministry of Local Government in giving effect to this resolution."

An Abortive Meeting of the Irish Medical Association.

It is a curious symptom of the apathy in which the medical profession of Ireland is at present steeped that the annual meeting of the Irish Medical Association summoned for June 12th had to be postponed for want of a quorum. The quorum is 20, and after waiting an hour there were still only 16 members present. The ordinary members of the Association, and of the profession at large, seem to have lost all interest in medical organisation at the very moment when a strong professional organisation is most needed. If the present inertia on the part of the profession continues, not only will medical interests be sacrificed, but, what is more important, the cause of health reform will suffer.

REPORT OF THE JOINT BOARD OF RESEARCH FOR MENTAL DISEASE.

A REPORT of work carried out during the year ending May, 1924, under the Joint Board of Research for Mental Disease, of which Sir F. W. Mott, F.R.S., is the honorary director, has been issued. A portion of the special grant of £400 made by the Board of Control, which was reserved for the investigation of the Basal Metabolism in Mental Disorder, has been expended in the construction of a respiratory chamber of a type similar to that used by Prof. J. S. Haldane and Dr. Graham at the University of Birmingham Mines Department, and about 160 gas analyses have already been made. The Research Board has founded a scholarship, valued at £250 per annum, for the investigation of the pathology of mental disease; Mr. Dennis L. Woodhouse, M.Sc., who has been appointed the first scholar, is undertaking an investigation into the effects of hypnotic drugs upon animals, more especially in relation to their growth and basal metabolism. Under the direction of Dr. F. A. Pickworth the bacteriological, biochemical, and morbid anatomy sections of the research laboratory have been equipped and associated with the clinical work of the hospitals. Over 600 bacteriological examinations have been made; agglutination reactions have been carried out, and the Bordet-Wassermann complement-fixation tests are now done in the laboratory. Other mental hospitals in the provinces, if they desire to avail themselves of the facilities of the research laboratories at Hollymoor, are invited to join the Research Board, when they can send material for investigation according to a given scale of charges. Under the supervision of the honorary director an investigation into the action of tryparsamide in early general paralysis is being made; up to the present six cases have received treatment. The utility of bismoxyl supplied by Prof. Levaditi is under trial at the Maudsley Hospital. Investigations have been instituted to ascertain the extent of the existence of chronic septic foci in cases of mental disorder; an attempt has been made to determine the character of the infections and to correlate them with morbid processes in other tissues. A preliminary communication on the results of the radiography of the bony structures of the head revealing evidence in some cases of deep bony infections associated with the jaws and nasal passages was submitted for discussion to the Medico-Psychological Association's meeting held in London, July, 1923, and was published in the *Journal of Mental Science.* This line of research is being continued. Recently the Birmingham guardians have become associated with the City and University of Birmingham in supporting the Research Board; and on behalf of their Monyhull Colony for Mental Defectives have made a contribution to the funds of the Board, enabling them to utilise the facilities of the research laboratory. They also have representation on the Board.

THE "Chesterfield" silver medal in dermatology at St. John's Hospital for Diseases of the Skin, Leicester-square, London, W.C., has been awarded to Dr. E. J. Tyrrell.

THE Chemists' Exhibition and Empire Drug Trade Mart will be held from June 23rd to 27th in the Central Hall, Westminster, London, S.W. The exhibition will be open each day from 11 A.M. till 8 P.M.

Correspondence.

"Audi alteram partem."

THE SIMMINS APPEAL FUND.

To the Editor of THE LANCET.

SIR,—The final list of donations to this fund brings it to the gratifying total of £1315 6*s.* 4*d.*; the fund is now closed.

The committee which was formed to issue the appeal held several meetings and carefully discussed how best the money subscribed could be utilised. It was unanimously resolved that the interests of the children would be best served by spending the money entirely upon their education. A capital sum of £1250 was accordingly paid to the Commercial Union Assurance Company in return for which a series of policies for each of the two children has been issued whereby for a period of ten years each child will receive a sum of £85 12*s.* 6*d.* per annum from the time it reaches the age of 9 years. After negotiations with the Royal Medical Benevolent Fund and with the kind coöperation of the hon. secretary, Dr. Newton Pitt, who has keenly interested himself in the matter, the committee is happy to report that the Royal Medical Benevolent Fund has agreed to administer, in conjunction with Dr. Nabarro, the monies payable under the said policies, and to apply the same, as and when received, for the education of the children. It is fortunate for the children that the Royal Medical Benevolent Fund is thus interested in them, because the members of the Ladies' Guild will no doubt also help the relatives to look after their well-being. Of the balance of the money collected—namely, £65 6*s.* 4*d.*—the sum of 3 guineas has been paid in connexion with the legal expenses incurred by the Royal Medical Benevolent Fund, leaving a sum of £62 3*s.* 4*d.*, which has been handed over to the relatives.

In conclusion, we should like to add that we are very grateful to all those, both in and out of the profession, who have so kindly interested themselves in the case, either by contributing to the fund or by their offers of adoption. In particular we would thank Mr. Herbert Semon and Mr. James Stobart who were able to secure for the fund £106 14*s.* and £31 15*s.* from members of the Stock Exchange and Lloyds respectively. Mention should also be made of the generous donations received from past and present members of Dr. Simmins's old schools at Westminster and Guy's Hospitals. Our thanks are also due to you, Sir, for the gift of valuable space, for without such coöperation the necessary publicity could not have been given to this deserving case.

We are, Sir, yours faithfully,
W. HALE-WHITE,
Chairman of the Appeal Committee.
H. C. SEMON,
Treasurer.
DAVID NABARRO,
Secretary.

Final List of Subscriptions to the Simmins's Appeal Fund.—Anon (Amara, Mesopotamia) and H. R. Leach, £10 each; J. B. Smith, £3 3*s.*; Dr. Petrie, £2 12*s.* 6*d.*; Cash, £2 2*s.*; J. B. Russell, £1 1*s.*

LEAD AND CANCER.

To the Editor of THE LANCET.

SIR,—The reply to Prof. E. L. Collis's comments (THE LANCET, June 14th, p. 1239) on my recent address, which is reviewed very fairly in your leading article (June 7th), is contained in the address in question (*Public Health*, June, 1924, p. 217). I would suggest that Prof. Collis do me the honour of reading it, for evidently he had not done so when he wrote his letter. I refrain from taking advantage of so obvious a controversial gift. I would, rather, ask the assistance of Prof. Collis in arriving at the truth, which can only be reached along the lines indicated in my address.—I am, Sir, yours faithfully,

June 14th, 1924. W. BLAIR BELL.

ENCEPHALITIS LETHARGICA AND NASAL DOUCHES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 7th, p. 1175, there is printed the section of the Memorandum on Encephalitis Lethargica issued by the Ministry of Health giving, amongst other directions, some "Precautions against Infection." Here it is suggested that—

> "those in contact with the case may be advised to use antiseptic nasal sprays or douches and to gargle the throat with solutions such as those advised for influenza. For example, any of the following: 1. One per cent. solution of peroxide of hydrogen. 2. A solution of permanganate of potash, 1 in 5000, in 0·8 per cent. solution of chloride of sodium (common salt). 3. Liquor sodæ chlorinatæ, 0·5 per cent."

Now, when this Memorandum suggests that "these solutions can be used as ordinary throat gargles," I do not think anyone can object to their use. They may certainly be helpful in cleansing and disinfecting the mouth and pharynx—cavities which are only able to protect themselves against bacterial invaders and their products either by expectorating them or by swallowing them into the stomach. There is nothing in the three suggested remedies to damage the mucosa of the mouth and pharynx. But a very different question is raised when it is advised that they should be "snuffed up the nostrils or applied by an efficient spray." The nasal cavities in health are very sensitive and highly organised chambers. The ordinary nerves of sensation, with which they are freely supplied, resent any irritating liquid and any antiseptic, except in such a weak solution as to be useless. The olfactory nerves are readily deteriorated by the use of any but warm, alkaline lotions, isotonic with the blood, and if they are benumbed one of the defensive mechanisms of the nose is weakened. The much more important defensive arrangements supplied by the normal mucus of the Schneiderian membrane, the ciliated epithelium, and the delicate mechanism of the turbinal bodies would all be interfered with by using any of the three suggested solutions as a nasal douche or spray. It is nearly 30 years since Prof. R. T. Hewlett and myself demonstrated that the interior of the healthy nose is a sterile cavity, that the nasal mucus in health is inhibitory to bacterial growth, and that the ciliated epithelia are active and never resting "chuckers-out" of any invaders.

The practical application of these researches is shown by the general disposition of rhinologists to abstain, when possible, after operation, from the use of powders, antiseptics, or plugs in the nose. An antiseptic, to be of any bactericidal value, would have to be of such a strength that it would produce a quite intolerable irritation of the nasal mucosa. Where milder antiseptics have been used, and benefit has been claimed from them, any good effect has doubtless been due to the stimulation of an increased flow of mucus. In conditions of disease, such as ozæna and syphilis, where the sense of smell, the ciliated epithelia, and the turbinal bodies have been all more or less destroyed, the circumstances are different. The nose is then a septic cavity, its sensitive and defensive mechanism are lost, and stronger antiseptics can be used with benefit. During previous influenza epidemics I have seen several cases of damage to the middle ear, and to the accessory sinuses, in patients who had taken their advice from the daily press and had been sniffing Condy's fluid up their nostrils.

It would be well, therefore, if the Ministry of Health's recommendations limited the use of these three lotions to their employ as gargles and mouth washes. The healthy nose provides for its own sterility, and this cannot be improved on. Blowing is all that is required for cleansing it of used-up mucus. If the nose falls below a standard of health—becoming either catarrhal or stenosed—it can be assisted, without harm, by using warm, alkaline lotions, isotonic with the blood. The simplest and readiest is normal saline solution. Others can be made by dissolving 10 gr. of borax or 6 gr. of soda in an ounce of water. Or several of these alkalis can be mixed together and prescribed in the strength of 5 gr. to the ounce. A little white sugar or glycerine or a mild antiseptic (menthol, sanitas, thymol, and the like) in a minute dose may be added to give a pleasant flavour. But all antiseptics are irritating to the nasal mucosa; in a normal nose they are useless and in efficient strengths they are harmful.

I am, Sir, yours faithfully,
StClair Thomson.
Wimpole-street, W., June 11th, 1924.

"INDUCTION" OR "CAUSE" OF CANCER.

To the Editor of The Lancet.

Sir,—My letter to you induced Dr. Archibald Leitch to answer it. The cause of his answer depended upon his agreement or disagreement with me and included the states of his hereditary history, digestion, nervous and vascular systems, to say nothing of his internal secretions. The middle of the first paragraph of his letter contains a sentence which shows he really agrees with what I wrote. I recognise this with great relief and pleasure, because it induces me to believe that the complicated physiology of my learned friend is normal. The diphtheria bacillus can induce in the same individual such opposite effects as diphtheria and immunity thereto, the causes of which are wrapped up in the mysteries of susceptibility and immunity respectively, by which subjects much labour has been induced.

I am, Sir, yours faithfully,
G. Lenthal Cheatle.
Harley-street, W., June 13th, 1924.

To the Editor of The Lancet.

Sir,—May I be allowed to endorse the view expressed by Sir Lenthal Cheatle in his letter on this subject in your issue of June 7th? I would particularly comment upon the following sentence: "It will be well to realise that factors that induce carcinoma belong to a quite different category from those that cause it." I think this is a timely reminder in view of a tendency noticeable at the present time to search for the causes of cancers. (I use this term to include both carcinoma and sarcoma.) My own view, in which I do not think I am by any means alone, is to consider cancer as a specific disease, which has a specific cause. Surely the predisposing factors cannot be regarded as the actual cause? Apart from some known or probable inducing factors, such as tar, soot, certain oils, pipe-smoking, betel-nut chewing, the kangri-custom, to mention only a few, there must be very many others if we are to account for all forms of cancer, of which those induced in the above-mentioned ways constitute only a minute proportion. It seems to me, were the manifold predisposing factors all known, we should scarcely dare to live, lest, by failing to avoid any one of them, the actual cause might be set up.

Four years ago, in the course of a leading article[1] on the Cause of Cancer, it was said: "Adami is more in line with modern conceptions of the cancer process as a profound alteration of cell metabolism when he ascribes malignant disease to an alteration in the activities of the cell, whereby function" (i.e., its specialised function) "becomes lost and only the power of growth remains." That is it; a fundamental alteration in the vital activity of the cell, which *may* be set up (or may *not* be set up: in the great majority of natural cases it all depends on the vital condition of the cell) by any one of various inciting or accessory factors. A long time will probably elapse before we understand the real nature and reason of this pronounced—yet, in my view, not really so remarkable—change in the mode of life of *certain individual* cells of a particular type. May I say that I think efforts might be more concentrated on ascertaining in what different manner a cancerous cell is behaving from a normal one. What is the characteristic and essential *expression* of its altered metabolic activities?

In the first place, the great thing to bear in mind is that the tissue cells are little *animals*—homologues of the unicellular protozoa. I know, of course, that this is generally regarded as the only reasonable and logical view to take; but I think this point is too much taken for granted, without attention being sufficiently paid to the important consequences that follow. And I think protozoologists should do all in their power to emphasise this homology, because of its bearing on progress towards understanding the nature of many of the diseases of still unknown causation. For nearly four years I have been trying to show that tissue cells ingest and (or) digest solid, organised nutriment, notably red blood corpuscles, but also cells. They do this both normally and in pathological conditions. I have termed this behaviour hæmatophagy and hæmetaboly. Normally, this function is exercised for the welfare of the body as a whole, and results in the production of various substances of the nature of "secretions" or "excretions." When a particular type of cell becomes deranged by the action of a ferment-virus, abnormal alteration of the blood elements results and various well-known and characteristic bodies and granules are produced. Ultimately, too, the cells themselves break down, when more bodies and granules are produced as a result of karyolysis.

In cancer, I think something quite different occurs. The vital alteration of the cancerous cell is such that it takes to metabolising and utilising the blood elements *for its own growth and proliferation*, instead of performing this function for the well-being of the body as a whole. In other words, this is a modification of Dr. Charles Creighton's view; and I would venture to draw the serious attention of others to this hypothesis. What is urgently required, I think, is more light on the question of the blood-digestive enzymes of tissue cells, and of the cell antibodies to such enzymes.

I am, Sir, yours faithfully,
London, June 13th, 1924. H. M. Woodcock.

"CONSTRUCTIVE CONSCIOUS CONTROL OF THE INDIVIDUAL."

To the Editor of The Lancet.

Sir,—It is evident that your reviewer (The Lancet, May 17th, p. 1007) has misunderstood, and consequently unwittingly represented my work, in that he has suggested that my conclusions, as set forth in the book with the above title, are those of an "intuitionalist" rather than the result of concrete procedures. I wrote in the preface, "I intend, in this volume, to adhere to my earlier scheme of practical illustration, endeavouring, as far as possible, to give a *demonstrable* illustration in connexion with statements and arguments," and I here repeat that I should have great pleasure in demonstrating to your reviewer the practical working of any of the principles which I advocate. I am certain that you are anxious that The Lancet should be a medium for making known the truth from whatever source it comes, and that you will not be prejudiced against me because I am merely a layman.—I am, Sir, yours faithfully,

F. Matthias Alexander.
Ashley-place, Westminster, S.W., June 13th, 1924.

MEMORIAL TO THE LATE PROF. PETER THOMPSON.

To the Editor of The Lancet.

Sir,—A movement has recently been initiated among the students of the late Prof. Peter Thompson to provide some memorial in the University of Birmingham of his work as professor of anatomy from 1909 to 1921. It has been suggested that his many friends and old pupils in Manchester and London would be glad of an opportunity of helping to keep his memory green. A general committee has been formed and it is proposed to raise a fund to be called the "Peter Thompson Memorial Fund." The ultimate decision as to the form of the memorial should take will depend on the amount which is subscribed, but the general feeling appears to be that the foundation of an annual prize in anatomy would be appropriate. A circular letter has been sent out, but we feel that many who would like to contribute to this fund may have been overlooked.

---

[1] The Lancet, 1920, ii., 705.

Subscriptions should be sent to either of the secretaries of the fund at 52, Newhall-street, Birmingham, and cheques made payable to the "Peter Thompson Memorial Fund" and crossed Lloyds Bank.—We are, Sir, yours faithfully,

JAMES C. BRASH,
Chairman.
LEONARD G. PARSONS,
HILDA N. SHUFFLEBOTHAM,
Hon. Secretaries and Treasurers.

THE PSYCHOLOGY OF SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—Will you kindly permit one who has spent much of his life afloat, commencing in a troopship at the age of a few months and only severing his connexion with the sea after some 17 years spent in all manner of craft, from destroyers and cruisers to battleships and liners, to offer a few observations on the psychology of sea-sickness. Dr. W. H. B. Stoddart is of the opinion that "sea-sickness is always of psychical origin." I confess to being mystified by this statement. "Psychical" is the adjective of "psyche," and by the latter I presume he means "mind." Now "mind" is an abstraction, a *mot de convenance* for the innumerable and multifarious *processes* taking place in brain substance, more especially, probably, in the cortical association areas. Sea-sickness, in my opinion, originates in "things" and not in "processes." Had Dr. Stoddart expressed the opinion that sea-sickness originates in the brain, one could, at any rate, even if disagreeing, have understood what he meant, but to maintain that it originates in a "psyche" is to confuse an abstract function with a concrete substance.

My acquaintance—longer than I care to think of—with this distressful malady as experienced in myself and exemplified in others convinces me that the only rational way to consider it is from a standpoint that regards the organism and the enviroment as an interconnected whole. If the relationship existing between the organism and environment be disturbed in a certain manner sea-sickness ensues. The ultimate origin of sea-sickness is obviously extra-organismal. The peripheral sense-organs convert environmental stimuli into centripetal nerve impulses which, streaming inwards by different routes eventually—that is, after integration and coördination by the cortical neurons—give rise to certain sensations, states of consciousness, and centrifugal nerve impulses that characterise the giddiness, nausea, faintness, sweating, retching and vomiting, &c., of sea-sickness. It is failure on the part of the organism correctly to interpret the resulting coördination of the several streams of nerve impulses flowing cerebropetally from the end-organs of orientation and movement that constitutes the basis of sea-sickness. The unpleasant sights, sounds, and smells, the stuffy, over-heated and vitiated air, incidental to a sea voyage in rough weather, are but powerful contributory factors. Short of stepping ashore and stopping ashore there is only one cure for sea-sickness, and that is adjustment of the conflicting impressions by the brain—adaptation. Under normal conditions the senses of orientation and movement, as derived from nerve impulses originating in the muscles, articular surfaces, in the walls of the otolith organ and semicircular canals, receive confirmatory evidence from corresponding nerve impulses emanating from the organs of vision. In sea-sickness the ingoing messages are utterly contradictory—in short, eye belies ear. Deaf-mutes, in whom the otolith organ is defective or absent, cannot be made giddy by forcible rotation, and are stated to be practically exempt from sea-sickness. There is, again, the evidence afforded by the "phantom swing." This is an apparatus that looks exactly like an ordinary swing attached to the ceiling of a room. In reality it is attached to an axis around which the whole room is capable of rotating; the "swing" itself never moves. When the room is oscillated about the sitter through a gradually increasing arc, the impression he receives from the eye are those of being himself swung, but these impressions are in conflict with those from his other organs of balance and movement (the semicircular canals and otolith receptacle) which are transmitting "messages" to the effect that he is not in motion. This confusion of the sensorium not infrequently results in giddiness, nausea, and even vomiting.

Dr. Stoddart believes that the rise and fall of a boat during a sea-voyage tends to remind certain people "in an unconscious way" of "the respiratory rise and fall of the mother's breast" when, as infants, they were being suckled, and that the sea-sickness with its rejection of food is a mode of repressing this infantile memory. He disposes of the objection that artificially fed infants also grow up into individuals prone to sea-sickness with the explanation that these were either nursed against the mother's breast whilst sucking their feeding-bottles, or else this was "supplemented or replaced by jigging the child to and fro or up and down, cradle-rocking, swinging, and so forth." Possibly, too, their "oral libido" was at too high a potential. May I ask him whether he would further stretch this already severely strained and far-fetched theory so as to include lower animals, such as dogs, who are frequently sea-sick, but who are not, as in the case of the human infant, suckled at pectoral mammæ, nor "jigged," nor "cradle-rocked," and who have no thumbs of their own nor fingers of a nurse to increase their "oral libido"?

It is questionable if those who go down to the sea in ships will gather either sense or comfort from Dr. Stoddart's remarkable assertion that his "explanation of sea-sickness will never cure a patient suffering from it. To be effective, he must discover the explanation for himself, out of his own mind." There are a goodly number of vaunted cures for *mal de mer*, most of them harmful, all of them useless, but an explanation out of one's own mind is a distinct novelty in the way of nostrums.

I am, Sir, yours faithfully,
C. MARSH BEADNELL,
Surgeon Rear-Admiral, R.N.
Chatham.

HYPERGLYCÆMIA AND GLYCOSURIA IN ACROMEGALY.

To the Editor of THE LANCET.

SIR,—In the paper by Dr. A. W. M. Ellis, published under the above heading in your issue of June 14th, no allowances have been made for the variations in the concentration of the blood that appear to take place after a meal in cases where there are disturbances of the functions of the pituitary. Possibly the apparent diminution of carbohydrate tolerance after the operation shown in this case by the percentage of sugar in the blood may be partly accounted for by variations in the blood volume resulting from the test-meal. With reference to the theory Dr. Ellis advances to explain the glycosuria of acromegaly, I may say that the metabolic experiments on animals upon which Mr. H. A. H. Howard and I are at present engaged have given results which tend to support his view, for they suggest that pituitrin is chemically antagonistic to insulin, and that, unlike adrenalin, it does not produce its effects on carbohydrate metabolism by directly influencing the formation of sugar from stored carbohydrate in the body, but by preventing the action of insulin in that direction.

I am, Sir, yours faithfully,
P. J. CAMMIDGE.
Nottingham-place, W., June 16th, 1924.

THE VALUE OF ARC-LIGHT BATHS.

To the Editor of THE LANCET.

SIR,—We have recently been extending here the application of the general arc-light bath, which has been proved useful by Reyn, Sequeira, and others, using a powerful long-flame arc, rich in ultra-violet rays, and exposing the back and front of the body in turn, at first for 5 and finally for 30 minutes, three or four times a week. Such baths notably put up the hæmobactericidal power of the blood, as tested in vitro (Colebrook, Eidinow, and L. Hill). Not only cases of surgical tuberculosis—e.g., a tuberculous hip—and cases of lupus have benefited very considerably from such baths, but also several women, of sedentary indoor occupation, who were suffering from sciatic or "rheumatic" pains, and were generally feeling run down in health. There has also been much benefited a case diagnosed on reasonably sure grounds (X ray evidence, &c.) as one of duodenal ulcer. This man had not been benefited by dietetic treatment, and an operation was discussed.

Perhaps the most interesting and surprising case was that of a man, aged 54, suffering from high blood pressure (220 mm. Hg systolic), breathlessness on climbing stairs, fainting attacks, frequent headaches for three years, and irritability. He had no signs of syphilis or renal disease, and had been previously treated in accordance with the best current medical opinion. Thus, he ate little meat and generally restricted his diet, neither smoked tobacco nor drank alcohol, gently exercised himself in the open air, and had hot baths. Nevertheless, his symptoms had continued unabated. After starting the arc-light baths his headaches vanished, and now, after two months, his symptoms have all gone, together with about 2 st. of his over-weight, his systolic pressure has fallen to 175, and he feels a different man.

Another striking case is that of a girl 16 years of age, ill in health, with approximately a 50 per cent. increase of lymphocytes, diminished polymorphs, a few myelocytes in her blood, the hæmoglobin down to 74 per cent., the abdomen somewhat distended, and a few glands in the right iliac fossa. While some grave disease of the blood-forming organs was considered possible, a doubtful diagnosis of tuberculous peritonitis was made. This girl, together with her blood, has been put into healthy condition by a two months' course of general arc-light baths.

Our daily measurements of ultra-violet radiations, taken with the acetone-methylene-blue gauge, have shown us the great loss of these rays in our cities compared with the open country. By indoor occupations and amusements, by screens of glass, smoke, and clothing, people cut themselves off almost entirely from the ultra-violet rays which in the winter in our climate are naturally weak. The vast metabolic organ formed by the living cells of the epidermis is removed from its natural stimulus—sunlight and open air. Hence, the very great benefit given to a variety of sickly people by arc-light baths. We predict that in two or three years the taking of such baths will become general as a winter pick-me-up.

We are, Sir, yours faithfully,

ALBERT EIDINOW.
LEONARD HILL.

National Institute for Medical Research, Hampstead,
London, N.W., June 17th, 1924.

BRITISH ORTHOPÆDIC ASSOCIATION.—The Association offers a prize of £50 and a medal to be given by Sir Robert Jones for an annual competition amongst members of the association of all grades for an essay on a subject in orthopædic surgery. The subject of the essay for 1924 is the Diagnosis, Treatment, and End-Results of Tuberculous Disease of the Hip-joint. The subject of the essay for 1925 is the Classification and Differential Diagnosis of the Different Forms of Arthritis. The essay is to be submitted typewritten, together with any illustrations and specimens, and forwarded to the Secretary, at 1a, Portland-place, W., on or before Dec. 31st in each year. It must not bear the name of the writer, but should be identified by a motto.

Obituary.

ROBERT BRUCE FERGUSON, M.D. CAMB., D.P.H.

Dr. Ferguson, who died at Surbiton on June 10th, was educated at Cambridge University and St. Mary's Hospital; at the former he graduated in arts and medicine, taking his M.D. in 1895. After qualifying he devoted himself for some time to ophthalmology, holding appointments as house surgeon at the Royal Westminster Ophthalmic Hospital, and clinical assistant at the Royal London Ophthalmic and St. Mary's Hospitals. Later he settled in New Southgate, where in addition to general practice he did ophthalmic work, his knowledge in that branch being much appreciated by his fellow practitioners. He was on the staff of the Passmore Edwards Hospital, Wood Green, and for a time chairman of the council. Dr. Ferguson was author of a useful little book entitled "Aids to the Mathematics of Hygiene," which went through five editions, and he contributed papers on diplopia and vertigo to medical journals. Latterly he had been living in retirement at Epping. He leaves a widow, three daughters, and a son, who with a large circle of medical and other friends will mourn their loss.

RICHARD EMMETT, M.D. DURH., M.R.C.S. ENG.

BY the death of Richard Emmett on June 8th Portsmouth loses one of its best-known public men, and a prominent and much-loved medical practitioner of the older school. Born in 1858 of good West country stock, he received his medical education at St. George's, and after qualifying in 1885 settled down to practise in Portsmouth. Here he quickly established a reputation, not only for professional skill and devotion, but for an ever-ready practical sympathy with all forms of distress. In the days when the standard of Poor-law nursing was low he offered himself as a candidate for the board of guardians with the object of raising that standard and securing the provision of a properly trained nursing staff. In this he was successful, in spite of opposition. He subsequently joined the town council, of which he remained a member for many years. He took an active part in the management of the Royal Portsmouth Hospital. Dr. Emmett was a keen Territorial officer, rising in 1914 to the rank of Lieut.-Colonel, R.A.M.C. It was overwork with his duties as senior medical officer in the district during the war years, in conjunction with the heavy calls of a large general practice which apparently brought on the serious cardiac condition which has now proved fatal. Dr. Emmett was made a J.P. in 1915. He was a man who touched life at many points, was a loyal friend, and a kind and sagacious physician.

CLARENCE ALFRED JOSEPH WRIGHT,
F.R.C.S. EDIN., F.R.F.P.S. GLASG.

Mr. C. A. J. Wright, of Leytonstone, who died last month in his fifty-ninth year, was a son of Dr. Arnold Wright, surgeon to the Rajah of Mysore. He was born in India and studied medicine in Madras, where at the Presidency Medical College he acted as demonstrator in anatomy. Later he went to Edinburgh and continued his studies at the Royal College of Physicians, obtaining the triple qualification L.R.C.P. & S. Edin. and L.R.F.P.S. Glasg. at the age of 23, and was admitted to the Fellowship of these bodies in 1898. Mr. Wright settled in Leytonstone about 26 years ago after some experience of practice in Rochester. He held several appointments in connexion with shipping and insurance companies and was certifying factory surgeon. He became a keen student of medical electrology and of nervous affections, and was for a time associate editor of *Medical Electrology and Radiology*. He was also editor of the *Archives of Rontgen Ray and Treat-*

ment. He wrote several treatises on electro-medical subjects; in 1904 he published an English translation of Freund's "Radio-therapy" and the following year, in the Transactions of the British Electro-Therapeutical Society, an article on Electrical Methods of Local Medication. He also contributed to *Treatment* an article on the Physiological Aspects of Radio-therapy Effects of Radiation upon the Immunising Powers of the Blood. Among his contributions to THE LANCET there appeared in 1904 several letters deprecating the practice of electro-medical treatment by lay persons.

EDWARD CHICHESTER, M.B. LOND.

Dr. E. Chichester, who died recently at Colchester, in his fifty-ninth year, after a long and painful illness, was a well-known East Sussex medical practitioner and honorary surgeon to the Essex County Hospital, of which he was also vice-president. He was educated at Friar Park, Bath, and studied medicine at the London Hospital, qualifying M.R.C.S. and L.R.C.P. in 1891 and M.B. three years later, with honours in anatomy. He subsequently held appointments as house surgeon and resident accoucheur at the London Hospital, and was clinical assistant at the Royal London Ophthalmic Hospital. In his younger days Dr. Chichester was an enthusiastic sportsman and a keen traveller. He was a descendant of the ancient family of Chichester, of Caverleigh, Devon, and was the fourth son of Captain Nugent Chichester. He is survived by a widow, two sons, and a daughter, to whom we extend our sympathies.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the College, held on June 12th, Sir John Bland-Sutton, President, in the chair, Dr. Arthur Robinson, professor of anatomy, University of Edinburgh, was introduced and after signing the by-laws was admitted a Fellow of the College.—The secretary reported the death of Prof. Samuel George Shattock, F.R.S., pathological curator of the museum, and the following vote of condolence was passed:—

> The Council hereby express their deep regret at the death of Prof. Samuel George Shattock and their sincere sympathy with Mrs. Shattock and the members of her family in their bereavement. In doing so the Council desire to place on record their high appreciation of Prof. Shattock's services to the College as pathological curator of the museum during 27 years, and they believe that the great collection of pathological specimens, to which he devoted such care and attention, will stand as a lasting memorial of his skill and knowledge. His wide experience, sound judgment, and accuracy of observation made him pre-eminent as a surgical pathologist in this country, and his loss will be greatly felt not only at this College, but also by many members of the profession who sought his advice and opinion.

The following gentlemen were elected examiners for the ensuing collegiate year in the subjects indicated:—

Diploma of Fellow.—Anatomy: Messrs. W. E. Le Gros Clark (St. Bart.'s), W. F. Haslam (Birmingham), F. G. Parsons (St. Thomas's), and William Wright (London). Physiology: Messrs. David H. de Souza (King's Coll.), J. Beresford Leathes (Sheffield), John Mellanby (St. Thomas's), and Ffrangcon Roberts (Cambridge).

Conjoint Board.—Elementary Biology: Messrs. J. P. Hill (Univ. Coll.) and T. W. Shore (St. Bart.'s). Anatomy: Messrs. Henry A. Harris (Univ. Coll.), David Hepburn (Cardiff), and Oscar S. Hillman (Middlesex). Physiology: Messrs. George A. Buckmaster (Bristol) and C. A. Lovatt Evans (St. Bart.'s). Midwifery: Messrs. Eardley Holland (London), C. Hubert Roberts, Donald W. Roy (St. George's), and H. Beckwith Whitehouse (Birmingham).

Sir Berkeley Moynihan was re-elected a representative of the College for the ensuing three years on the Court of Governors of the University of Sheffield.

As the result of the Final Fellowship Examination, held from May 22nd to June 5th, for which 96 candidates presented themselves, 24 candidates were approved. Four of the successful candidates (Arthur John Gardham, John Percival Hosford, Laurence Frederick O'Shaughnessy, and Frederick Hector Scotson) have not yet attained the requisite age and will not receive the diploma until a later date. The Diploma of Fellow was therefore conferred upon the following 20 candidates:—

> William S. Adams, Birmingham and London; Edward P. Brockman, Cambridge and St. Thomas's; Digby Chamberlain, Leeds; Joseph M. Craig, St. Andrews and Guy's; Cecil A. Horder, St. Bart.'s; Philip J. Jory, Otago and St. George's; Cyril A. King, Otago; Reginald C. B. Ledlie, Guy's; Robert C. B. Macrae, Edinburgh and London; Ida C. Mann, Royal Free and St. Mary's; Alan E. Park, Otago and London; Vithaldas L. Parmar, Bombay and Guy's; Conrad V. Patrick, Cambridge and St. Thomas's; Gordon H. Pfeiffer, Sydney, Middlesex, and Guy's; Esther Rickards, St. Mary's; Allan Seddon, Liverpool and London; Harold G. Taylor, Cambridge and St. George's; Arthur H. C. Visick, St. Bart.'s; William R. Williams, Liverpool; and Edric F. Wilson, Guy's.

CAMBRIDGE MEDICAL GRADUATES' CLUB.—A dinner of this club will be held on Friday, June 27th at 7.30 P.M., at Cambridge, in Trinity College. Any member who wishes to be present is asked to inform the Secretary, Mr. W. H. C. Romanis, F.R.C.S., 31, Harley-street, W. 1, as soon as possible.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The eighty-third annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held on July 1st, 2nd, 3rd, 4th, and 5th, under the presidency of Dr. M. J. Nolan, at the Medical Institute, College-square, Belfast, and Queen's College, Belfast. On July 1st Dr. F. R. Martin will read a paper entitled the Reaction of the Blood to the Ingestion of Protein in the Psychoses. On July 2nd, after a business meeting, a paper will be read by Dr. T. Houston on the Examination of the Cerebro-spinal Fluid, to be followed by two short papers read by Dr. W. Calwell: (1) The Unconscious, a Suggestion; (2) Short Notes on a Case of Cerebral Sanguineous Cyst with Mental Symptoms following Surgical Relief. In the afternoon the presidential address will be delivered by Dr. Nolan, and a visit will be paid to Purdysburn Villa Colony. On July 3rd, in the morning, a paper will be read by Dr. A. T. Hobbs, of Toronto, entitled a Survey of American and Canadian Opinion as to Focal Infections as Causative Factors in Functional Psychoses. Dr. R. Marshall will contribute some notes on Encephalitis Lethargica, and Prof. G. M. Robertson will read a paper entitled Is Dementia Præcox a Definite Clinical Entity? Demonstrations and pathological specimens will be on view. In the afternoon a paper will be read by Dr. Chalmers Watson entitled Further Reflections on the Rôle of Auto-Infection in the Ætiology of Acute and Chronic Mental Disorders, and in the evening the annual dinner of the Association will be held. On July 4th a visit will be paid to Downpatrick Asylum. At 11.30 A.M. Sir Frederick Mott will read a paper entitled the Thyroid Gland in Bodily and Mental Disease, to be followed by a paper by Dr. W. R. Dawson on the Work of the Belfast War Hospital, 1917–19. For July 5th various excursions have been arranged. The Maudsley Lecture nominee for next year will be Dr. Shaw Bolton.

OXFORD OPHTHALMOLOGICAL CONGRESS.—The fifteenth annual meeting will be held on July 3rd, 4th, and 5th, Sir Anderson Critchett, the Master, presiding. The Congress will be opened with an address of welcome by the Master at 10.30 A.M. on July 3rd, and at 10.45 a discussion on the General Principles of the Treatment of Convergent Concomitant Strabismus will be opened by Dr. E. Landolt and Dr. E. Thomson. Those taking part include Dr. G. E. de Schweinitz, Mr. T. Harrison Butler, Mr. R. Beatson Hird, Mr. Ernest Clarke, Mr. A. F. MacCallan, Mr. Claud Worth, Mr. Angus MacGillivray, Dr. Stewart Barrie, and Dr. Marion Gilchrist. The annual general meeting will afterwards be held. The afternoon will be devoted to demonstrations in the Scientific and Commercial Museums. At 7.45 P.M. the annual dinner of the Congress will be held in the Hall of Keble College. On July 4th, at 10 A.M., Dr. Howard F. Hansell will describe Four Cases of Atypical Retinitis Pigmentosa Associated with Developmental Abnormalities and Occurring in Members of One Family, and Dr. Harry Friedenwald will discuss: (1) Retinal Vascular Changes in Young Persons, Associated with Various Retinal Diseases; (2) Relation of Chorio-Retinitis Juxtapapillaric (Jensen's Disease) to Other Forms of Chorio-Retinitis. At 11, the Doyne Memorial Lecture will be delivered by Mr. T. Harrison Butler, the subject being Focal Illumination of the Eye with Special Reference to the Clinical Use of the Gullstrand Slit-Lamp. At 12.15 P.M., Dr. F. Park Lewis will speak on Preventive Ophthalmology as an Organised Movement. The remainder of the afternoon will be spent at the Eye Hospital, when demonstrations with Corneal Microscopes and Gullstrand slit-lamps will be given by Mr. Harrison Butler, assisted by Mr. R. J. Coulter, Mr. B. Cridland, and others. On July 5th, at 10 A.M., Mr. H. H. Joy will read a paper on Ophthalmology from a Legal Aspect. Demonstrations in the Scientific Museum will be given by Dr. George Young, Dr. Rayner D. Batten, Dr. Thomson Henderson, Dr. H. M. Traquair, Mr. J. H. Tomlinson, Mr. A. H. MacCallan, Mr. P. H. Adams, Mr. T. Harrison Butler, Dr. Arthur Greene, and Miss R. Millauro.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—This Association will hold its annual meeting at the British Medical Association, 429, Strand, London, W.C., on June 26th, at 3 P.M., when Sir Arthur Newsholme, the president, will deliver an address.

MEDICAL GOLFING SOCIETY.—The annual summer meeting was held at the Sunningdale Golf Club on June 12th. In spite of the bad weather 77 members took part in the tournament. All play was on the old course. The results were as follows: THE LANCET Cup: H. Gardiner-Hill (scratch) 78, 1 up on bogey. Henry Morris Cup: W. R. Bristow (4), 2 up. Class I.: 1st, E. Ravensworth Hart (9), all square; 2nd, C. E. Finny (7), 1 down. Best last nine holes: Sir R. Cruise (2); W. H. Lamplough (1), 1 up. Class II.: 1st, Murray Thomson (10), all square; 2nd, G. Norman (10); C. Gregory (15), 2 down. Best last nine holes: L. Lack (13), J. Bright Banister (18), all square. In the Foursomes the following three couples tied for 1st place at 3 down: E. R. Hart (9) and H. W. Carson (15); G. Sutherland (8) and B. Hamilton (12); M. Page (5) and W. R. Bristow (4).

AN ITALIAN MEDICAL JOURNEY.—A medical tour to the main spas of Italy has been organised by the Italian State Tourist Department (known as the E.N.I.T.) and will take place from Sept. 18th to Oct. 3rd next, under the guidance of Prof. Guido Ruata, M.D., General Secretary of the E.N.I.T. The following spas will be visited: Acqui, S. Pellegrino, Levico, Vetriolo, Roncegno, Salsomaggiore, Bagni di Montecatini, Monsummano, Chianciano, Fiuggi, Agnano. At each spa visited a lecture will be given to illustrate its medicinal qualities, followed by visits to the establishments. The lectures will be delivered in Italian by a medical authority of the station, and copies in French, English, and German will be supplied to the visiting doctors. Doctors to act as interpreters in French, English, and German will accompany the tour. The party will be limited to 200, and the tour is intended solely for members of the medical profession; a certain limited number of tickets, however, will be available for relatives of the participants. The complete charge of the tour is fixed at 1600 lire, including first-class travel and hotel expenses from the starting point at Milan to the conclusion at Naples. The participants will also benefit by a reduced fare from the Italian frontier to Milan—valid from Sept. 6th, and from Naples to the frontier—valid up to Oct. 20th. The application list will be closed when the total of 200 has been reached, and not later than July 31st under any circumstances. Full particulars and application forms may be obtained from the Travel and Tourist Office of the E.N.I.T., 12, Waterloo-place, Regent-street, London, S.W. 1.

PUBLIC HEALTH: THE BORDEAUX CONGRESS.—The congress held at Bordeaux by the Royal Institute of Public Health during and after Whitsuntide was characterised by the practical nature of the communications that were read. In the section of general State medicine and in that of the special hygiene attaching to military and air service, admirable opportunities were given for close comparison between British and French methods, while the interchange of experiences in industrial medicine was fruitful. And this was to be expected, for the British representatives included some of our best-known practical workers, and they sat beside their distinguished French similars. Considerable space and time was allotted to the transactions of the sections dealing with women and public health, and from the medical point of view the most important debates of the congress centred round the care of women and children. Mrs. Massey Lyon described the various child welfare organisations in Great Britain, and the Vicomte Pelleport-Burete described the organisation for the care of puerperal women which is maintained at Bordeaux. An interesting contribution came from Dr. Catherine Chisholm, the medical inspector of the Manchester High School for Girls, who pointed out that examining bodies which failed to see that they were unduly taxing youthful powers were incurring grave responsibilities. Her general conclusions on the matter of physical education of adolescent girls pointed out that physical training should be corrective and educational as well as recreational, and should be distributed over the curriculum and not be relegated to one particular day. In the same section papers were read which instituted interesting comparisons by Mdlle. St. Luc, of Bordeaux, and by Miss Cummins and Miss Phyllis Lyall, respectively almoners at St. Thomas's Hospital, London, and the Maternity Hospital, Glasgow. Miss Lyall well represented the directions of modern opinion in pointing out the need for appropriate Government intervention in respect of the problems of illegitimacy, and revision of the present law in relation to illegitimacy and adoption. French law is more liberal-minded than British law.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.—Applications are invited for the following bursaries under the scheme for a permanent memorial to the late Miss Lucy Robinson: (1) £20 to a student in training for conjoint examination, massage, and medical gymnastics; (2) £20 to a masseuse who gained the I.S.T.M. certificate in massage, was a member of the I.S.T.M., and is a registered member of the Chartered Society, as assistance towards qualifying further in medical gymnastics or medical electricity. Further particulars may be obtained from the Secretary of the Society, 157, Great Portland-street, W. 1, to whom applications for bursaries must be sent not later than June 30th.

DONATIONS AND BEQUESTS.—The late Mrs. Alice Theresa Lucas left by will £1000 to Guy's Hospital, and £10,000 to that institution in certain contingencies which also applies to £5000 to the National Society for the Blind; £5000 to the Hospital for Consumption and Diseases of the Chest, Brompton; £3000 to the Belgrave Hospital for Children; £3000 to the Chelsea Hospital for Women; £3000 to the Victoria Hospital for Children, Tite-street, Chelsea, S.W., and Broadstairs, Kent; £3000 to the London Hospital; £3000 to the Jews' Deaf and Dumb Home, Nightingale-lane, S.W.; £1000 to the Hospital for Women, Soho-square; £500 to the National Society for the Prevention of Cruelty to Children; £500 to the Cancer Hospital, Brompton; and £500 to Queen Alexandra's Hospital Home for Discharged Soldiers.—By the will of the late Mr. Edwin Heard, of Liverpool, the testator left £200 to the Liverpool Royal Infirmary; £100 to the National Institute for the Blind; and all other his property to the Royal Liverpool Children's Hospital.

MILLER GENERAL HOSPITAL FOR SOUTH LONDON.—A dinner is to be held in connexion with the endeavour which Lord Queenborough, the president of this hospital, is making to raise the sum of £46,000 for the hospital extensions. The institution was founded in 1783 as the Kent Dispensary, and has from that time steadily increased in size and utility, though it is still far too small for the needs of the population to which it ministers. King Edward's Fund for London has approved an extension which will eventually mean the addition of 336 beds. At the present moment the hospital has 100 beds, but this is only made possible by utilising the board room, the matron's office, and other administrative accommodation as a ward—obviously an unsatisfactory arrangement. The immediate proposal is to build one more ward block of three wards, giving 78 beds, a main kitchen, stores, and also the first section of a home for nurses. For these additions £46,000 are required, of which £24,000 only are in hand. A sketch of the proposed ward blocks and of the nurses' home is contained in an informative pamphlet which is being sent out from 39, Berkeley-square, London, W. 1, by Lord Queenborough, to whom applications for dinner tickets should be made.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society was held on June 13th, at the house of the Royal Society of Medicine, 1, Wimpole-street, W., Lord Lamington, the President, being in the chair. There was a good attendance of members. A satisfactory report of the work done by the society during the past year was submitted, in which among other things it was pointed out how great was the contrast between the present conditions as regarded the attitude of the public towards research and conditions as they were in 1908, when the society was founded. The treasurer stated in his report that the finances of the society were in a satisfactory condition, and that subscriptions and contributions from branches exceeded those of 1922 by £115 and donations by £22. The reports having been passed unanimously, Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, then gave a demonstration of a cinematographic film illustrating the natural history of malaria and the preventive method against that disease. This film had been prepared and was lent by the International Health Board of the Rockefeller Foundation. Dr. Balfour began by emphasising the need of the experimental spirit for the development of medicine, and he quoted Sir William Osler in showing that the whole work which has been done on malaria was based on experiments on animals. Sir Ronald Ross's work in India also depended on experimental work on animals, and Dr. Balfour, in pointing out how essential such work was, said that no man of sense or sensibility would use animals to experiment on if he could possibly avoid it. The film shown was one that had been prepared in America to give a vivid and simple picture of the ravages of malaria, particularly for the benefit of the agricultural population of the Southern States. The life-history of the plasmodium was well depicted, and stress was laid on the various methods of breaking the chain of infection at one or other of its links, whether by stamping out the mosquito, rendering man immune by quinine, or by guarding him from the bites of the insect by means of netting. At the conclusion of the film Sir Ronald Ross thanked Dr. Balfour, and pointed out that our present knowledge of malaria had existed for a quarter of a century, yet it was only now that an attempt was being made to tackle the problem efficiently throughout the world.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—An extraordinary meeting will be held at 11, Chandos-street, London, W. 1, on Friday, June 27th, at 8.30 P.M., when the plans for publishing a journal will be laid before the members of the Society.

LANCASHIRE AND CHESHIRE SOCIETY FOR THE PERMANENT CARE OF THE FEEBLE-MINDED.—The annual meeting will be held in the Mayor's Parlour of the Manchester Town Hall on Thursday, June 26th, at 3.30 P.M., the Lady Mayoress presiding.

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY, JUNE 16TH.

Retrenchment in Indian Army Hospitals.

Colonel Sir **CHARLES YATE** asked the Under Secretary of State for India whether, considering the disastrous effects in Mesopotamia of the retrenchment in hospitals establishment in the army in India carried out in pre-war days, the India Office was prepared to sanction the proposed reduction of 1957 beds in British and 2041 beds in Indian station hospitals, of 15 officers of the Indian Medical Service, and 60 assistant surgeons.—Mr. **RICHARDS** replied: These reductions have been or are in process of being carried out, with the sanction of the Secretary of State where that was required. They are partly due to reductions of combatant strength, and in any case will not seriously affect the improvements introduced since the experience of Mesopotamia.

Indian Assistant Surgeons.

Mr. **HOPE SIMPSON** asked the Under Secretary of State for India how many assistant surgeons of the Indian Medical Department were dismissed during the financial year 1923–24, and how many it was proposed to dismiss during the current financial year; whether any representations had been received on this subject; and whether, in view of the very serious unemployment among Anglo-Indians at the present time, the Government of India could take steps to avoid reduction of cadre until some of the unemployed had been able to obtain other work.—Mr. **RICHARDS** replied: A reduction of 92 assistant surgeons has been sanctioned, including 32 who are in excess of the establishment, but it is not known how many of these were discharged in 1923–24. Certain representations on this and other matters relating to the Anglo-Indian community have been received and transmitted to the Government of India. As in the case of other services, retirements are being carried out on favourable terms, and I fear I cannot hold out hope of any exceptional measures in the case of this department to mitigate the hardship involved in the reductions.

Sale of Patent Medicines.

Mr. **WALTER BAKER** asked the Minister of Health whether in the interests of the health of the community and as some return for the heavy taxation imposed in the form of medicine duty, he would introduce legislation to enable patent medicines to be sold under licences only issuable after an impartial examination of the merits of the proprietary articles.—Mr. **GREENWOOD** replied: My right hon friend fears that in the present state of Parliamentary business it would be impracticable to attempt legislation on this subject this session.

TUESDAY, JUNE 17TH.

A National School of Medicine.

Sir **BEDDOE REES** asked the President of the Board of Education whether the Government had any information concerning the reasons that had led the Council of the University College, Cardiff, to oppose the establishment of an independent national school of medicine, in accordance with the recommendations of the Royal Commission on University Education in Wales.—Mr. **MORGAN JONES** replied: My right hon. friend has himself no information on this matter, which does not fall within the province of the Board of Education. He has, however, made inquiries and understands that it has been the subject of correspondence between the Privy Council and the promoters of a Supplemental Charter for the University College of South Wales and Monmouthshire. The Privy Council, in letters dated Feb. 1st and March 14th, 1923, regarding the Draft Supplemental Charter submitted to them on behalf of the College, gave their reasons for objecting to the complicated scheme therein proposed for the government of the National School of Medicine, and for holding that the interests of the school would be best served by its establishment as an independent unit within the University, on the lines recommended by the recent Royal Commission. The Privy Council, in reply to an inquiry, were informed on Jan. 24th last that it was hoped that the Council of the University College would at an early date be in a position to submit a report to the Court of Governors of the College on the matter; up to the present time, however, no further communication with regard to it has been received by their lordships from the promoters of the Supplemental Charter.

R.A.M.C. Vacancies.

Lieut.-Colonel **ASSHETON POWNALL** asked the Secretary. of State for War if he would state what action it is intended to take to fill the many hundred vacancies for lieutenants in the Royal Army Medical Corps.—Mr. **S. WALSH** replied: There has been a reduction in the establishment of R.A.M.C. officers, and the vacancies are not so numerous as his question would imply. The number of vacancies is only about 40 at present, and I hope that a large proportion of these will be filled as the result of next month's entrance examination. Beyond this I can add nothing to my previous replies, in which I indicated that the present shortage was receiving careful consideration.

VOLUNTARY HOSPITALS COMMISSION.

THE Conference of Local Voluntary Hospitals Committees was held on June 18th at the Ministry of Health, Lord Onslow, chairman of the Commission, presiding. The morning session was opened by the Minister of Health, Mr. Wheatley, who expressed the appreciation of the Ministry for the work the local committees had done already for the public welfare. Lord Onslow outlined the present position. The Commission was instituted two years ago to deal with the distribution of half a million pounds sterling from Government to make up the maintenance deficits. This sum had been administered in three distributions, which were completed in March of this year. He stated that the Conference had been called mainly to discuss the inquiry, undertaken by the Commission at the request of Parliament, into the extent of the voluntary hospital accommodation required in England and Wales, and the best means of providing and maintaining it.

A questionnaire had been sent out to the local hospital committees and had brought in a large number of replies. He said that the situation of the hospitals was now very much more favourable than when Lord Cave's Committee furnished their report, and that now few hospitals had beds closed through lack of money. The question of extensions was in a better position to-day; it had not even been contemplated three years ago. Out of a total of 216 hospitals reported upon, there were 99 who communicated the need for extra beds.

Thereafter representatives of the local hospitals committees gave their views on the problems presented in their own special areas, and it was noted that three points in particular received emphasis from many speakers. First there was the question of greater need for recovery and convalescent beds in order to relieve the pressure on the accommodation of the central hospitals; secondly, the question of the Poor-law infirmaries was dealt with, and it was felt that no use could be made of these institutions by the voluntary hospital type of patients until the stigma of the Poor-law had been removed. Thirdly, the question of paying wards was raised. This was held by several to be an asset to the voluntary system, and a suggestion was made as to how far the voluntary hospitals might carry out the work of the public health authorities if paid for such work, particularly with respect to the treatment of surgical tuberculosis. In order to arrive at a definite conclusion as to the actual proportion of beds required for the population, it was urged that a detailed analysis of hospital waiting lists be made, and the advisability was suggested of issuing another questionnaire in order to obtain the views of general practitioners throughout the country on this subject.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, June 23rd.

ODONTOLOGY: at 8 P.M.

Papers:

Mr. Ivan S. Spain and Mr. F. N. Doubleday: Ultra-Violet Radiations, Their Use and Limitations in Dentistry.

Prof. A. Hopewell-Smith (Univ. of Pennsylvania): The Non-innervation of Dentine (illustrated by a series of lantern slides, photomicrographs and sections under microscopes).

N.B.—The sections under microscopes, illustrating Prof. Hopewell-Smith's paper, will be in position by 7.30 P.M.

Tuesday, June 24th.

Hospitality to Visitors from the Dominions.

A special Social Evening to welcome the medical men from overseas now in London will be held at the Society's house on Tuesday, June 24th. The guests will be received by the President, Sir William Hale-White, and Lady Hale-White at 9 P.M.

The Library will be open, and various objects of interest will be shown. Music, light refreshments and smoking.

At 9.45 P.M. a short Address will be given by the President in the Robert Barnes Hall, on The Story of "Say Ninety-nine!"

Thursday, June 26th.

UROLOGY: at 8.30 P.M.

Discussion:

On Polycystic Disease of the Kidney, to be opened by Sir Thomas Horder and Sir Bernard Spilsbury.

Paper:

Dr. Parkes Weber: Lipoid Speckling of the Renal Cortex—the So-called "Myelin Kidney."

Will those desiring to take part in the discussion send in their names to the Hon. Secretary, Mr. Girling Ball, 77, Wimpole-street, W. 1, as soon as possible.

Thursday, Friday, and Saturday, June 26th, 27th, and 28th.

LARYNGOLOGY }
OTOLOGY } Combined Summer Meeting.

Friday and Saturday, June 27th and 28th.

STUDY OF DISEASE IN CHILDREN: Provincial Meeting at Liverpool.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.

SATURDAY, June 28th.—A special meeting at King George V. Sanatorium, Godalming.

MONDAY.—The ordinary quarterly meeting at 122, Harley-street, London, W.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 23rd, to SATURDAY, June 28th.—CHELSEA HOSPITAL. Daily Operations, &c. Mon., 2 P.M., Mr. J. B. Banister: Backward Displacement. Wed., 2 P.M., Mr. John Ellison: Vaginal Discharge. Thurs., 9.30 A.M., Mr. F. L. Provis: Sterility. Fri., 2 P.M., Mr. Comyns Berkeley: Cervical Fibroids.—CHILDREN'S CLINIC. Mon., 2 P.M., Dem. of Cases. 4 P.M., Dr. H. E. Archer: Biochemical Investigation of Gastro-Intestinal Diseases. Wed., 2.15 P.M., at Crossroads Club, 88, Alexandra-road, St. John's Wood, Dem. of Baby Cases. 3.30 P.M., Dr. Bernard Myers: The Nutritional Disturbances of Infancy. Thurs., 10 A.M., At Children's Clinic, Dem. of Cases. 11.30 A.M., Mr. Rocyn Jones: Birth Palsies and their Treatment. —LONDON SCHOOL OF TROPICAL MEDICINE. Tuesday and Thursday at 2 P.M., Demonstrations on Diseases of Tropical Countries.—ROYAL NORTHERN HOSPITAL, in conjunction with the Royal Chest Hospital, City-road. Special Course in Intensive Medicine and Surgery (second and last week, as per syllabus).—ST. PETER'S HOSPITAL FOR STONE. Clinical Work and Special Lectures daily (second week, as per syllabus).

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-street, W.C.

THURSDAY, June 26th.—4 P.M., Dr. Hutchison: Affections of the Liver in Children.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

TUESDAY, June 24th.—5 P.M., Dr. Gray: The "Eczemas" of Infants and Children.

THURSDAY.—5 P.M., Dr. Dore: Psoriasis.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, June 26th.—5 P.M., Mr. Richard Lake: Intra-Cranial Complications of Middle-Ear Diseases. (Geoffrey E. Duveen Lectures in Otology.)

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, June 23rd.—12 noon., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Addison: Surgical Wards.

TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Pernet: Skin Dept. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—11 A.M., Dr. Archer: Chemical Pathology. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M., to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE.

MONDAY, June 23rd.—12 noon, Dr. Riddoch. Lecture: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Birley. Lecture: Tuberculi Combined Degeneration of Spinal Cord.

TUESDAY, June 24th.—12 noon, Dr. Greenfield. Lecture: Cellular Reaction in Nervous System. 2 P.M., Dr. Walshe, Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Clinical Lecture.

THURSDAY, June 26th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes. Lecture: Syphilis of Nervous System.

FRIDAY, June 27th.—2 P.M., Dr. Gordon Holmes: Out-patient Clinic. 3.30 P.M., Mr. Sargent. Lecture: Tumours of Ponto-Cerebellar Angle.

Applications should be addressed to the Secretary, Medical School, National Hospital for the Paralysed and Epileptic, Queen-square, London, W.C. 1.

J. G. GREENFIELD, Dean.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

MONDAY, June 23rd.—(At the Children's Hospital.) Mr. Leathart: Clinical Cases.

TUESDAY.—(At the Southern Hospital.) Dr. W. Johnson: Neurasthenia.

THURSDAY.—(At the Stanley Hospital.) Mr. A. Evans: Surgical Condition of the Gall-Bladder.

FRIDAY.—(At the Royal Infirmary.) Mr. Litler Jones: Surgical Cases.

UNIVERSITY OF BRISTOL POST-GRADUATE STUDIES. (Bristol Eye Week, June 23rd to 28th, at the Bristol Eye Hospital.)

MONDAY, June 23rd.—10 A.M., Mr. Godby Gibbs: Spectacles. 2.30 P.M., Mr. Godby Gibbs and Mr. E. R. Chambers: Demonstration of Cases.

TUESDAY.—10 A.M., Mr. E. R. Chambers: Glaucoma. 2.30 P.M., Mr. Richardson Cross and Mr. A. E. Iles: Demonstration of Cases.

WEDNESDAY.—10 A.M., Mr. Cyril Walker: Choroiditis. 2.30 P.M., Mr. Cyril Walker: Demonstration of Cases.

THURSDAY.—10 A.M., Mr. A. E. Iles: Significance of Hæmorrhages of the Fundus Oculi. 2.30 P.M., Mr. Godby Gibbs and Mr. E. R. Chambers: Demonstration of Cases.

FRIDAY.—10 A.M., Mr. Richardson Cross: The Occipital Lobe and the Field of Vision. 2.30 P.M., Mr. Cyril Walker: Demonstration of Cases.

Pathological specimens illustrating each subject will be demonstrated daily by Dr. A. D. Fraser.

Appointments.

ROFFEY, B. W., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Surgeon, St. Bartholomew's Hospital, Rochester.

Jessop Hospital for Women, Sheffield: LEATHES, Prof. J. B., F.R.C.P. Lond., F.R.C.S. Eng., F.R.S., Honorary Physiologist; STACEY, J. ERIC, M.D. Lond., F.R.C.S. Edin., Honorary Assistant Surgeon.

Royal Southern Hospital, Liverpool: TAYLOR, H., M.B., B.S. Lond., Hon. Asst. Orthopædic Surgeon; ROBINSON, A. L., M.D. Liverp., F.R.C.S. Eng., Gynæcologist.

St. John's Hospital for Diseases of the Skin, Leicester-square: FRAZER, E. HASLETT, M.A., M.B., B.Ch., GREEN, L. J., M.R.C.S., L.R.C.P. Lond., and MUIR, D. C., M.B., B.S., Clinical Assistants.

Certifying Surgeons under the Factory and Workshop Acts: DYSON, R. J., M.B., Ch.B. Leeds (Pickering); FAIRWEATHER, J. W. C., M.B., Ch.B. Edin. (Fordoun).

Vacancies.

For further information refer to the advertisement columns.

Bahamas.—Bacteriologist and Asst. M.O.H. £600.
Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—P. 100 guineas.
Bradford City.—M.O. £600.
Brighton, Sussex Maternity and Women's Hospital.—Hon. S.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.
Derbyshire Education Committee.—School M.O. £600.
Dudley Guest Hospital.—H.S. £200.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. £125.
Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. £150.
General Lying-in Hospital, Lambeth, S.E.—R.M.O. £100.
Gilbert and Ellice Islands Colony.—Sen. M.O. £650.
Hong-Kong Government.—Two M.O.'s. Also Asst. Port Health O. Each £600.
Hull Institution and Infirmary, Anlaby-road.—R.M.O. £500.
Liverpool, Royal Southern Hospital.—Hon. Asst. P. and Hon. Asst. S.
Manchester, St. Mary's Hospitals.—Three H.S.'s Each £50.
National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. Path. £250. Also R.M.O. £200.
Putney Hospital, Lower Common, Putney, S.W.—Res. M.O. £150.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Sen. Res. M.O., Two Asst. Res. M.O.'s. £100 and £80 respectively.
Reading, Royal Berkshire Hospital.—Third H.S. £150.
Rochdale Infirmary.—M.O. in charge of X Ray, &c., Dept.
Royal Chest Hospital, City-road, E.C.—P. in charge of Out-patients.
Royal Ear Hospital, Dean-street, Soho.—Registrar. £50.
St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.—Pathologist. £100.
St. Mary's Hospital for Women and Children, Plaistow, E.—Clin. Asst.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.
St. Thomas's Hospital.—Visiting Anæsth.
University College Hospital, Gower-street, W.C.—Asst. to Venereal Dis. Dept. £250. Also Hon. Anæsth.
University of London.—External Examiners.
West London Hospital, Hammersmith-road, W.—Asst. Anæsth.
Windsor, King Edward VII. Hospital.—Asst. P., Asst. S., Clin. Assts., and Anæsth.
Wolverhampton and Staffordshire Hospital.—Res. Surg. O. £250.
Wrexham Infirmary.—H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Portsoy, Banffshire; Bo'ness, Linlithgowshire; Portsmouth, Hampshire; Handsworth, Yorks, West Riding.

Births, Marriages, and Deaths.

BIRTHS.

ABEL.—On June 7th, at Clifton-hill, N.W., the wife of A. Lawrence Abel, M.S., F.R.C.S., of a son.

HARRIS.—On June 12th, the wife of Noel Gordon Harris, M.R.C.S., L.R.C.P., of a daughter.

LLOYD.—On June 9th, at Kensington Hall-gardens, W.. the wife of Vernon E. Lloyd, M.C., M.B., B.S., M.R.C.S., L.R.C.P., of a daughter.

MACLEOD.—On June 7th, at 52, Baxter-gate, Loughborough, Leics, to Dr. and Mrs. Neil MacLeod (née Ruth Hill, M.B., Ch.B.)—a son.

SAVY.—On June 11th, at Sonnhalde, Kingussie, the wife of Felix Savy, M.B., Ch.B., of a son.

MARRIAGES.

COLES—BAGSHAWE.—On June 3rd, at St. John's Church, Bournemouth, Alfred Charles Coles, M.D., D.Sc., F.R.S. Edin., to Frances Edith, third daughter of the late Richard Bagshawe, of Nottingham, and of Mrs. Fenn, Cheveley, Surrey-road, Bournemouth.

GASKILL—GRIFFITH.—On June 13th, at the Streatham Wesleyan Church, Dudley Keverne Gaskill, L.D.S., to Gwyneth Griffith, elder daughter of Mr. and Mrs. Richard Hooson Griffith, Streatham.

DEATHS.

EMMETT.—On June 8th, at "Winton," London-road, Portsmouth, suddenly, Richard Emmett, M.D., J.P., aged 66 years.

FERGUSON.—On June 11th, Robert Bruce Ferguson, M.A., M.D. Camb., D.P.H., &c., age 60.

JOHNSON.—On June 14th, at Shalimar, Sidmouth, Major Valentine Goode Johnson, R.A.M.C.

RAPER.—On May 21st, after an operation, Matthew Henry Raper, M.D. Lond., of Valletta, Godalming, formerly Shoeburyness.

SMITH.—On the 8th inst., at St. Mary's Hospital, London, Matthew Baird Smith, B.Sc., M.B., Ch.B. Edin., of Stroud, Gloucestershire, aged 39.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

COLONIAL HEALTH REPORTS.

FEDERATED MALAY STATES.

FROM a report signed by Mr. W. G. Maxwell, C.M.G., Chief Secretary to the Government, it appears that the census taken on April 24th, 1921, shows that the population of these States (Perak, Selangor, Negri Sembilan, and Pahang) was then 1,324,890, of whom 853,528 were males and 471,362 females. The Chinese population was 494,548, being 61,304 more than in 1911. Practically the whole of this increase was in Chinese females, who now number 351 to 1000 males, as compared with 188 in 1911, and the lessening disparity between the sexes among the Chinese is gratifying as indicating a general tendency towards their permanent settlement in the Federated Malay States. In 1921 the Indian population totalled 305,219, as compared with 58,386 in 1901, the increase being due to the development of the rubber-planting industry. The European population rose from 3284 in 1911 to 5686 in 1921, of whom 93·2 per cent. were of British nationality. The most satisfactory feature of the census is that all the statistics—of sex, of marriage, of age, and of birth-place—show that the immigrant races, who have done so much to develop the resources of the Federated Malay States, are ceasing to look upon these States as a place of temporary sojourn and are tending more and more to make their permanent home here. There were in 1922 34,906 births and 35,028 deaths, the rates being 25·65 and 25·74 per mille respectively. The death-rate is the lowest recorded for 12 years. Deaths of children under 1 year of age numbered 5963, being an infantile mortality rate of 170·83 per mille. As usual, malaria heads the list as the most important cause of sickness and death. The number of deaths recorded was 15,570 (11·44 per mille). The public, though slow to undergo indoor hospital treatment for venereal diseases, is keenly appreciative of the facilities now afforded to outdoor patients. Injections of novarsenobenzol were given to 19,690 persons. Comparatively few cases of gonorrhœa come for treatment. A systematic campaign against yaws makes good progress. In 1922 injections of novarsenobenzol were given to 22,972 persons. as against 12,207 in 1921. In certain districts the disease has been almost eradicated. The Malays travel long distances to obtain treatment. The number of vaccinations was 65,201 as against 68,280 in 1921. It will be noticed that the vaccination-rate far exceeds the birth-rate. As regards infectious diseases, 1 case of plague, 18 of cerebrospinal meningitis, and 16 of small-pox are all there is to report. There was no case of cholera. At the instance of the Infant Welfare Advisory Board an enactment for the registration of midwives was passed during the year. At the Board's request, also, the Government has made arrangements for the training both of midwives and the ayahs employed on estates. There are in the States the following medical institutions: 4 European hospitals; 40 district hospitals; 3 women's hospitals; 3 leper asylums; 7 jail hospitals; 1 quarantine camp (for immigrants); 4 vagrant or decrepit wards; 1 mental hospital; 14 outdoor dispensaries; and 10 town dispensaries. During the year there were 92,690 indoor patients as against 116,785 in the preceding year. Outdoor patients numbered 433,111 as compared with 329,310 in 1921. The decrease in the number of in-patients is largely due to the new town dispensaries, which are most successful and popular. The Mental Disorders Enactment, 1922 (repealing the Lunacy Enactment) marked a very important step; and much is meant by the fact that mental patients are no longer termed "lunatics." The arrangements for early voluntary treatment, and for temporary or conditional discharge should be most beneficial. On Dec. 31st, 1922, the patients at the only institution in the country (the Central Mental Asylum, Tanjong Rambutan) numbered 838 males and 212 females. It is noteworthy that although the number of malaria patients in the year must be some enormous figure, only 78 admissions to the asylum are attributed to malaria. Alcohol accounted for 64 admissions; and it is strange that there were more alcoholic cases amongst the Chinese than amongst Tamils (37 Chinese and 26 Tamils). It is still more strange that opium accounted for only 2 Chinese admissions. Syphilis accounted for 35 admissions. Investigations into the treatment of malaria by quinine and other alkaloids of cinchona have been continued, and details have been sent to the Cinchona Derivatives and Malaria Committee of the Medical Research Council in London. The campaign against malaria is far from being merely a matter of preventing the breeding of anophelines. Malaria is a human disease, and improved methods of its treatment as such will tend to diminish the chances of its being carried from man to man by the agency of the anopheline.

Interesting and important discoveries were made in respect of meliodosis (pseudo-cholera). Investigations of the protozoa of dysentery were continued, as also were studies of new methods of the diagnosis of syphilis.

Brunei.

Mr. L. A. Allen, British resident in Brunei (a native State on the north-west coast of the Island of Borneo), in his report for the year 1922, gives the total population as 21,748. Hitherto no births and deaths have been registered, but an Act for the Registration of Births and Deaths was to come into operation in 1923. A total of 1966 out-patients were treated in Brunei town and the out-stations. The more serious cases (45 in all) were sent to Labuan Hospital; the chief diseases of those admitted were: malaria 14, abscesses 7, venereal diseases 5, and amœbic dysentery 3. Malaria was rather more prevalent in 1922 than in 1921, 282 patients being treated. 87 children were examined for enlargement of the spleen and 16 showed definite enlargement. Ankylostomiasis is undoubtedly present in Brunei to a considerable extent. It is impossible to say how prevalent venereal diseases are as the natives do not come for treatment for gonorrhœa or primary syphilis. There were no cases of dangerous infectious disease in the State during the year. It is interesting to note that the last epidemic of such occurred in 1905-06, when Brunei was decimated by small-pox. Some 3000 vaccinations have been carried out during the past four years. At the beginning of 1922 there was an outbreak of "cholerine" in Brunei town, when many of the children died. The officer in charge reports on this as follows: "On investigating this disease I found that many adults were attacked also by diarrhœa and vomiting and violent cramping pains, but in all such cases a high temperature was present also. Very few adults died, however. The fruit season had just come in, fruit was plentiful, and all the cases I saw had eaten a lot of it." Between March and May there was an epidemic of whooping-cough in Brunei town and in the Temburong district, but the mortality from it was apparently very slight. Dr. T. A. C. Cleverton, Medical Officer, Labuan, was in charge of the department throughout the year, paying routine fortnightly visits from Labuan. His valuable advice and assistance in all health and medical matters connected with the State are much appreciated. The total rainfall in Brunei town for the year was 131·60 inches, which was above the average. The mean maximum shade temperature during the year was 86·99° F. and the mean minimum 73·85°, giving a mean temperature of 80·42°.

Kenya Colony and Protectorate.

Kenya may be described as situated astride the equator on the eastern side of the continent of Africa. The precise boundaries were proclaimed in the Order in Council of 1921. The southern boundary runs from the coast in a north-westerly direction, and those portions of the colony which are most suitable for European occupation lie in the highlands, from 1° to 2° south of the equator, and, in the case of the Uasin Gishu plateau, within 1° north. The Protectorate is a strip of territory along the coast line up to the Tana River, ten miles broad. It includes also the station of Kismayu in Jubaland, with a radius of 10 sea miles landward from that town. It is 2200 square miles in extent and forms part of the dominions of the Sultan of Zanzibar, from whom it is leased at a rent of £17,000 a year. Kenya Colony comprises the remainder of the territory—viz., 242,860 square miles. There was happily no outbreak of any epidemics in 1922. Immediate treatment was accorded to sporadic cases of plague, and the rat destruction campaign was efficiently maintained. The general public health has been satisfactory, but there is, naturally enough in a young and growing community, which finds itself at the moment financially embarrassed, ample scope for improvement. The problem of native housing in the towns is acute, but there has been an effort to deal with it. In Nairobi a native location has been laid out under municipal auspices, and at the end of 1922 50 huts were in course of construction. The scheme was to be extended in 1923, and will serve as a model for other towns. Sanitary inspection is performed by officers appointed for the purpose in Nairobi, Kisumu, and Mombasa. The registration of births and deaths is not compulsory save for Europeans, and it is therefore impossible to furnish reliable figures of the birth- and death-rates amongst Asiatics and Africans. Such figures as there are serve to show that in Mombasa the crude death-rate is 16·7 per 1000 and in Nairobi 21 per 1000 of the population. The Nairobi rate is capable of analysis, and reveals crude death-rates for Europeans, Asiatics, and Africans of 12·4, 15·6, and 27·9 per 1000 respectively. Over the whole country the number of European births and deaths was 261 and 89, giving crude birth- and death-rates of 27·04 and 9·04 per 1000. The basis of the calculation of those rates is the 1921 census, and it may be safely assumed that owing to trade depression the number of natives has not increased. The figures of that census were: Europeans, 9651; Indians, 22,882; Goans, 2431; Arabs, 10,102; others, 627; total 45,633. The native population is estimated at two and a half millions. On the coast the year 1922 will live in the memory as the wettest year on record. In Mombasa 41·08 inches of rain were registered in the one month of May. In ordinary years the coast is fairly healthy for the tropics. The heat is a damp heat, and never compares with the fierce heat of India. The long rains fall in the months of April to June, and short rains during October, November, and December. The hot season is from January to March. In the highlands the heat is seldom oppressive. During the rains fires are welcome at night, and the climate generally is temperate, though the heat of the sun compels the wearing of helmets or terai from 8 A.M. to 4.30 P.M.

The Kenya Medical Journal.

We have received a copy of the first printed issue of the *Kenya Medical Journal*, which circulates throughout Kenya Colony, Uganda, Tanganyika, and Zanzibar. The journal has developed from a small beginning in cyclostyle form nearly a year ago, and is now launched with the coöperation of Mr. R. F. Mayer, of the *East African Standard*, Limited. It is intended for the distribution of medical news of local or general interest, and for the discussion of problems appertaining to medical science in all its branches. The first issue contains the report of an address given by Sir Arnold Theiler on recent investigations into plant toxins and deficiency diseases of stock in South Africa, which, in view of its great interest, might well have been more detailed than it is. The papers include an analysis of 14 cases of lobar pneumonia in the prison hospital at Nairobi, a case of obstructed labour treated by Cæsarian section (wrongly spelled), and a preliminary report on a new bismuth preparation for the treatment of yaws, being a suspension of precipitated metallic bismuth in 50 per cent. glucose solution. The journal is to be published monthly at a cost of 2*s.* a number, or 21 shillings 50 cents for the year, posted in Kenya. The editor may be addressed at Box 641, Nairobi.

INADEQUATE FEES FOR ATTENDANCE ON MILITARY PATIENTS.

Should a soldier fall ill when distant more than a mile from an officer of the Army Medical Service, or from a medical officer of the Special Reserve, or from a civilian medical practitioner engaged by the War Office at contract rates, he is entitled to treatment at the hands of a private medical practitioner on the basis of a tariff set out in Army Form O. 1667. Women on the married establishment of their respective corps and children under 14 years of age enjoy the same privilege. For such attendance the private practitioner must state on his bill the nature of the case, the dates of his visits, and whether or not medicine was supplied. We learn from the tariff that the ordinary fee for a day-visit (including medicine) is 3*s.* 3*d.*, for a night-visit (including medicine) between 10 P.M. and 7 A.M., 4*s.* 6*d.*, distance being charged extra at the approximate rate of 1*s.* a mile in the day and 2*s.* a mile in the night. The fee chargeable for the visit of the military patient to the surgery of the private medical practitioner is 2*s.* The practitioner who sends us details of a case which he attended upon these terms remarks that the fees seem inadequate, and in this we agree, while we note red-ink alterations on the Army form indicating that the prices have been raised by 30 per cent. since this form was printed in 1915. Our correspondent has, no doubt, protested in writing against the inadequacy of the fees, and his protest, reinforced by those of other practitioners similarly situated, should result in further improvement.

A MORE EXCELLENT WAY.

A little volume has recently been published as a memorial to its author, a young medical woman, a member of the Society of Friends, who rendered great though unobtrusive services in connexion with various forms of relief work during the war. The play which gives its title to the volume [1] is described as a "Peace Drama of the Balkan War," and affords conclusive evidence of the thoroughness with which Dr. Thomas had thought out her peace position before the catastrophe of 1914. The book is frankly didactic, but to say this is not to disparage it. It contains passages of real beauty, although—as far at least as the prose sections of the play are concerned—it would have been much improved by a revision of the punctuation. A number of short poems, mainly pacificist and all with a strong religious tendency, conclude a book which is evidently the expression of an unusually attractive personality.

Croonian Lectures

ON

RESEARCHES ON LEPROSY
AND THEIR BEARING ON THE TREATMENT OF TUBERCULOSIS.

Delivered before the Royal College of Physicians of London

BY SIR LEONARD ROGERS, M.D. LOND.,
F.R.C.P. LOND., F.R.C.S. ENG., F.R.S.,
PHYSICIAN AND LECTURER, LONDON SCHOOL OF TROPICAL MEDICINE.

LECTURE IV.*—THE USE OF CHAULMOOGRATES AND MORRHUATES IN THE TREATMENT OF TUBERCULOSIS.

Delivered on June 26th, 1924.

As early as October, 1916, I recorded the opinion that "the reactions produced by gynocardates in leprous tissues, and the apparent destruction of Hansen's bacillus, raises the very important question as to whether some similar reaction may not be obtained in the case of another human acid-fast bacillus—namely, that of tuberculous disease." Shortly after I commenced giving sodium gynocardate orally in tuberculosis without obtaining any striking results, and also made some animal experiments to test my hypothesis, which failed owing to deficient virulence of my cultures of the tubercle bacillus, and late in 1917 I made sodium morrhuate, and, after finding it effective in leprosy, arranged for its trial in tuberculosis, and early in 1919[2, 3] reported on a year's trial of the drug by several experienced observers in India with some promising results, to which I will return after discussing the probable mode of action of the new preparations.

MODE OF ACTION OF CHAULMOOGRATES AND MORRHUATES.

In March, 1920, E. L. Walker and Marion A. Sweeney[4] recorded important tests of the action on acid-fast bacilli in vitro of the sodium salts of the different fractions of the fatty acids of chaulmoogra oil I had made and used in leprosy in Calcutta, and found that the highest melting-point one had little action, but my fractions B and C, which were effective in leprosy, were most active in killing various acid-fast bacilli which will grow in fluid media up to dilutions of about 1 in 100,000, but that the salts of chaulmoogric acid had little effect, and those of the total fatty acids were the most active. Moreover, this action on acid-fast bacilli was specific and 100 times as great as that of pure phenol, but no such effects were obtained against coli and other non-acid-fast organisms. On the other hand, sodium morrhuate and sodium linoleates had no such action, so they stated "we believe that it can be concluded with reasonable certainty that any therapeutic action which chaulmoogra oil may have in leprosy is due to its direct antiseptic and bacteriological action on *B. lepræ*," while they attributed this specific action to the carbon ring structure peculiar to the fatty acids of this oil, and that their results "furnish theoretical grounds for the application of the chaulmoogrates to the therapy of tuberculosis," as I had suggested nearly four years previously.

During the last few months Otto Schobl[5] in the Philippines has largely confirmed and extended Walker and Sweeney's results in a series of experiments in which measured amounts of 42 different oils were added to 10 c.cm. of glycerine agar media, and their effects in inhibiting the growth of inoculated human tubercle bacilli compared with control cultures. The results confirm very closely the conclusions of the earlier workers, although in solid media, in which only a portion of the soaps come into contact with the bacilli, the highest dilution producing complete inhibition of the growth of the tubercle bacillus was 1 in 10,000 in the case of *Hydnocarpus wightiana* oil, which was five times stronger than that of true chaulmoogra oil from *Taraxtogenus kurzii*, of *H. venenata* (Brill), *H. subfactata*, and *H. alcalæ*, confirming my earlier conclusion regarding the great activity of the *Hydnocarpus wightiana* in leprosy. Moreover, sodium gynocardates were the most active, and sodium hydnocarpate was 20 times as powerful as sodium chaulmoograte, again largely confirming my clinical trials. Of the numerous other oils tested only that of cinnamon oil equalled the action of chaulmoogra oils, but unlike the latter was equally powerful against non-acid-fast bacilli, while it is interesting to note that Cashew nut oil came next with one-tenth the action of cinnamon oil, as the former was used locally in leprosy in South America three decades ago.

DIFFICULTIES OF THE DIRECT ACTION THEORY OF CHAULMOOGRA DERIVATIVES.

I have pointed out two serious difficulties in accepting the direct action theory of chaulmoogrates on leprosy bacilli in vivo, for in the first place it will not explain the cases I have mentioned in which steady improvement over many months, and even complete recovery, following prolonged febrile reactions after even a single minute dose of sodium gynocardate intravenously, which could not possibly continue to destroy vast numbers of lepra bacilli in the tissues extending over many months; and secondly, this theory completely fails to explain the undoubted action of sodium morrhuate and the several other soaps against leprosy, which have little or no direct action on acid-fast bacilli in vitro, for Stanley Griffith[6] found that sodium morrhuate when added to solid culture media had no inhibiting effect on the bacillus, although other observers have found the whole cod-liver oil to inhibit its growth as I shall show presently, and in 1921 I came to the conclusion that the remarkable improvement often following febrile reactions produced by sodium gynocardate and morrhuate "appear to be best explained on the theory that, during the extensive breaking down of the bacilli, antigens are formed, which bring about the subsequent prolonged improvement. I have for long considered that the action of the soluble salts of the fatty acids of the several oils I have shown to be effective on leprosy must, in some way, be due to a chemical reaction with the fatty acids in the coating of the acid-fast bacilli, so weakening their protective envelopes as to allow the body cells to deal with them, while the extensive breaking down of the bacilli in the body may lead to immunising antigen formation in the system," and I advocated further research on the subject.

Lipase Theory.—My attention was next drawn by Dr. A. Shaw-Mackenzie to his paper[7] recording that the addition of 3 per cent. solutions of sodium gynocardate, morrhuate, or oleate to a pancreatic extract doubled the fat-splitting effect of the pancreatic lipase on an emulsion of olive oil at blood heat, which led him to suggest "a direct stimulating action of tissue lyposis in, at any rate, partial explanation of the therapeutic effect of sodium morrhuate and sodium gynocardate on acid-fast bacilli." This likely hypothesis led me to investigate the possibility of the substances I had been using, also stimulating the production of fat-splitting lipase in the blood of leprosy and tubercle cases, in the latter of which blood lipase has for some time been known to be reduced in progressive cases, and worked with the kind permission and help of Dr. Mackenzie Wallis in the biochemical laboratory of St. Bartholomew's Hospital.

Blood-lipase Variations in Leprosy.—I suspected that in nodular leprosy cases, with enormous numbers of acid-fast bacilli in the affected tissues, the blood lipases might be even more reduced than in tuberculosis with comparatively few bacilli, and I am immensely indebted to Dr. E. Muir for kindly comply-ing with my request for a number of sera of treated and untreated lepers, which he sent home in sterile ampoules, packed in ice, by sea from Calcutta to London, and I estimated the lipase contents, before looking at the notes of the cases, by the ethyl butyrate test with the following instructive results expressed in terms of c.cm. of decinormal sodium hydrate.

---

* For the first three lectures vide p. 1321.

Type of case.	No.	Highest figure.	Lowest figure.	Average.	—
Nodular untreated.	3	0·07	0·00	0·033	Very low.
,, treated ..	9	0·29	0·08	0·22	Normal.
Nerve treated ..	8	0·26	0·17	0·19	,,

The extremely low figures of the untreated nodular cases contrast in a striking manner with the normal rates of the treated of both types, no untreated nerve ones, unfortunately, being included in the series. Moreover, the only treated nodular case which showed a great reduction of the blood lipase—namely, to 0·08—proved to be one in whom a severe reaction had taken place very shortly before his blood was taken, during which it might be expected that the ferment would be used up in breaking down the bacilli, a supposition which was later confirmed by Muir in a long series of estimations he kindly carried out in Calcutta, regarding which he reported to me: "We are finding almost invariably a very low lipase content in severe reactions, and we are finding a good prognosis justified when there is a high lipase content."

We have in these observations a striking confirmation of the lipase theory of action of these preparations, for the great reduction of the blood lipase during the severe reactions, with sudden breaking up of enormous numbers of lepra bacilli, together with the high blood content in leprosy cases improving under the treatment with gradual dissolution and absorption of the bacilli, are both easily explained in accordance with the view that the drugs act by both increasing the amount of lipase in the blood and the stimulating action on this ferment indicated by Shaw-Mackenzie's experiments in vitro. Moreover, the action appears to be a vital tissue one, for Prof. J. B. Collingwood very kindly tried for me, at my suggestion, the action of lipases on tubercle bacilli in vitro with negative results.

It is also obvious that the lipase theory explains in a simple manner the activity in leprosy of soluble compounds of the unsaturated fatty acids of a number of oils, and not only that of chaulmoogra oil, as indicated by Walker and Sweeney's theory. Nor is this conclusion merely of theoretical importance, as it opens up an unlimited field of research in the preparation and trial of derivatives and their chemical compounds of many available oils in the hope of eventually finding still more potent remedies for both leprosy and tuberculosis. Indeed, much work has already been done towards extending the methods already proved of value in leprosy to the even more important problem of tuberculosis, to the consideration of which I must now turn.

DIFFICULTIES IN APPLYING THE TREATMENT TO TUBERCULOSIS.

In attempting to destroy the tubercle bacilli in the body on the lines found successful in leprosy it is essential to bear in mind the greater dangers and difficulties—firstly, owing to tuberculosis so frequently affecting vitally important organs in a manner very rarely seen in leprosy; and, secondly, to the more toxic nature of the tubercle bacillus. Even more serious is the danger of disseminating the organisms with possibly fatal results in view of the appearance of new lesions, with temporary aggravation of the condition sometimes occurring after reactions in leprosy induced by the new preparations. These reasons made me hesitate to try gynocardate of soda intravenously in tuberculosis, while it is irritating subcutaneously, and led me to turn to cod-liver oil and prepare sodium morrhuate, which is almost painless in a 3 per cent. solution subcutaneously. After ascertaining its apparent harmlessness in a few cases, I placed the drug in the hands of several reliable observers with greater clinical facilities than I possessed at the time, and at the end of a year's trial I published their reports verbatim [3] and a summary,[2] which brought out the following points. Dr. Muir reported febrile and local reactions in tuberculous glands, which might be followed by their almost complete disappearance, and similar reactions in lung cases of short duration with temporary increased expectoration, followed by the rapid diminution of both the sputum and the tubercle bacilli in it, and gain in weight and strength, although he did not claim any complete recoveries in the acute type of phthisis seen in Bengal. Major R. Knowles, I.M.S., also reported promising results, with marked gain in weight, in several cases of different types, and made the important observation that tubercle bacilli in the sputum became granular and badly staining as they decreased in numbers before completely disappearing, in a very similar manner to what I had found in leprosy. Dr. Caleb Davies reported very similar results to those of Muir, one case of tuberculous epididymitis and early lung affection clearing up and remaining well three years later, while Major C. I. Brierley, I.M.S., reported remarkable improvement in both a severe pulmonary and in an extensive gland and bone tuberculosis case; but, on the other hand, Lieut.-Col. A. W. R. Cochrane, I.M.S., observed only temporary improvement, but no bad effects, at the Bhowali Sanatorium in the Kumaon Hills, none of the observers having seen any ill-results even from 1 to several c.cm. of 3 per cent. sodium morrhuate intravenously, results which I felt justified me in recording in the hope that "sodium morrhuate will prove at least as useful as the tuberculin treatment now in such general use, and also much safer in the hands of the profession at large, many of whom had not the extensive experience necessary for the safe use of that double-edged weapon—tuberculin."

ANIMAL TESTS OF CHAULMOOGRATES AND MORRHUATES.

In 1920, on my return to England, I renewed my efforts to obtain evidence of the action of gynocardates and morrhuates on tuberculosis-infected rabbits and guinea-pigs, and through the kindness of Sir Walter Fletcher, secretary to the Medical Research Council, and of Dr. Stanley Griffith, arranged to work in the laboratory of the latter at Cambridge, the animals being infected with large doses of bovine and human tubercle bacilli, which killed controls within a few weeks with generalised disease, which Dr. Griffith considered necessary to get any certain results. Under these stringent conditions I failed to obtain any benefit from either sodium salts or ethyl esters prepared from chaulmoogra or cod-liver oils, and in recording these negative results I suggested that although "this research failed to show any beneficial effect from the preparations tested in animals with extremely little resisting power to general tuberculous infection, it does not necessarily follow that they are all useless in chronic tuberculosis in the more resistant human species." Recently Dr. H. Miller has kindly repeated these trials at the pathological laboratory at Midhurst, using large doses, and found the treated animals sometimes died before the controls. Dr. C. H. Browning has pointed out [8] that in mice a chronic form of tuberculosis more akin to that in man can be produced experimentally, and he has most kindly undertaken to test morrhuates in it.

Walker and Sweeney's in vitro tests of chaulmoogra derivatives have naturally led to similar animal experiments by others, the most comprehensive of which are those of C. Voegtlin, M. I. Smith, and F. M. Johnson,[9] in which many scores of guinea-pigs were used with ample controls, being infected with varying doses of tubercle bacilli from the minimal one of 0·001 mg., which only produced definite tuberculosis in 27 per cent. of the controls, through moderate doses up to sufficient to induce acute infections, but they found no evidence of any inhibitory effect of sodium chaulmoogrates, with or without calcium lactate, and concluded: "The net result of this exhaustive experimental test of the value of chaulmoogra oil and its derivatives is therefore negative." J. A. Kolmer, L. C. Davis, and R. Jager [10] as well as F. Leuret [11] obtained similar negative results, but W. L. Culpepper and Marjorie Ableson [12] and E. L. Walker himself [13] have recorded only slightly retarding effects on tubercle in guinea-pigs from these preparations.

CHAULMOOGRA DERIVATIVES IN HUMAN TUBERCULOSIS.

In the meantime gynocardates and hydnocarpates (gynocardate of soda A) were being tried clinically in accordance with my suggestion with the following results. In 1920 Max Biesenthal [14] recorded ten cases of phthisis treated with ten weekly intravenous injections of sodium gynocardate with no benefit, while one patient showed a marked extension of the physical signs in the lungs, indicating a focal reaction of undesirable degree, and in the following year T. J. Beasley [15] reported ten cases treated with Dean's ethyl chaulmoograte, and in two cases observed focal lung reactions like those produced by Koch's original tuberculin in large doses, marked improvement following in one only, and he noted decrease of moisture and increase of tubercle bacilli in the sputum, but no change in the morphology of the organisms, such as has been observed after sodium morrhuate. F. Leuret [11] also used my 3 per cent. sodium gynocardate in two cases with no effect in one, while the other subsequently improved, further trials being indicated, while recently I. D. Bronfin and C. Meckel [16] have reported in detail on the chaulmoogra oil preparations in laryngeal tuberculosis, and found it might cause progressive ulceration, but had no therapeutic value.

Through the great kindness of Dr. W. T. G. Pugh, medical superintendent of the Queen Mary's Hospital for Children at Carshalton, an extensive trial during the last 18 months of both ethyl hydnocarpate and sodium morrhuate has been carried out by Dr. Edna Mawson and Dr. V. F. Fry, to whom I am greatly indebted for reports on their experience. Focal reactions in the form of temporary increased discharge from sinuses was noted after both preparations, and ethyl hydnocarpate in one case of tuberculous kidney was unfortunately followed by generalised tuberculosis, while little benefit appears to have been derived from this chaulmoogra derivative, whose use has for some time been given up in favour of sodium morrhuate, which was also preferred to the hydnocarpate after a short trial at the Fazakerley Hospital of Liverpool.

Thus no definitely beneficial results have been obtained from the use of chaulmoogra oil derivatives in either animal or human tuberculosis, although focal reactions in the diseased tissues occur, sometimes of an injurious nature like those due to excess of tuberculin, subsequent improvement only occasionally being seen, and the results on the whole are very disappointing, no evidence of any direct action on the tubercle bacillus having accrued.

FURTHER CLINICAL TRIALS OF SODIUM MORRHUATE.

Since the publication in 1919 of my paper on the trials of sodium morrhuate in India a number of reports have appeared with variable results, of which the following is a summary. In April, 1920, Captain P. Gunguli, I.M.S.,[17] reported very favourably on its use in the dry, cool climate of Quetta in 37 phthisical sepoys, including only four early cases with steady improvement and disappearance of the tubercle bacilli from the sputum of the two positive ones, while of 28 advanced cases 14 were discharged "cured" by a medical board, 4 were improving, 3 stationary, and 4 died; unfortunately the recovered cases returned to their homes and their after-history could not be obtained. In December, 1920, Max Biesenthal [18] reported on 25 cases treated for an average of four months, 8 being incipient and 17 moderately advanced, but obtained variable and uncertain results, and although the physical signs improved in 16, were unchanged in 4 and in 5 progressed, his impression was that sanatorium cases did as well without the drug, although he thought the method should be tested further. In 1922 M. J. Fine [19] came to a very similar conclusion from the treatment of 1 incipient, 13 moderately advanced, and 1 advanced case of phthisis, and stated that the preparation "deserves further trial and may be placed in the category of aids to our usual treatment of tuberculosis."

W. D. Tewksbury [20] treated 18 cases, 2 with a fair and 16 with an unfavourable prognosis, all being in a moderately or far advanced stage of the disease, and found 9 improved, 6 not improved, while 3 died, and he concluded that "it is difficult to say that the improvement noted in the nine cases is due to the treatment, as we know how often patients of this type will display periods of temporary improvement without any treatment, but it is at least possible that the sodium morrhuate had some beneficial effect. I feel that while our results are not conclusive, they are sufficiently interesting to warrant further work and observation along the same line." This observer, as the result of repeated examinations of the sputum, states that "The most striking feature was the apparent breaking up of the tubercle bacilli in the sputum and the tendency to their diminution in number and disappearance. This was noted in 10 patients, and in two of these the sputum became entirely negative. This is an interesting and remarkable phenomenon when we remember that these were advanced, open cases, and as it occurred in more than half the series, could hardly be attributed to anything other than the sodium morrhuate." This confirms the observations of R. Knowles,[3] and indicates a specific action of the drug on the tubercle bacillus in vivo, in spite of a negative one in vitro, and the action in vivo is explainable on the lipase theory, although not on any direct action theory such as Walker's with regard to chaulmoogra derivatives.

In December, 1923, the late Dr. P. W. R. Boelke, of Sydney, in a lengthy paper,[21] claimed uniformly good results during four years' trial in all forms and stages of tuberculosis from 3 per cent. freshly prepared sodium morrhuate forming a clear solution at blood heat, given in small subcutaneous doses of 0·1 c.cm., increased by the same amount at each injection up to 1 c.cm., any local tuberculin-like reaction at the site of injection being an indication for reducing the dose. Illustrative cases with disappearance of the bacillus from the sputum were narrated, although the total number treated was not given, and trials by a number of experts at my request, unfortunately, have not fully confirmed his claims, but have yielded some interesting results which may now be summarised from the reports so kindly sent to me. The necessity of only using freshly-made clear solutions at blood heat, which Boelke lays stress on, is in accordance with the fact that I have for long known—namely, that unless sodium morrhuate powder is kept quite dry, which is not always easy in a hot, humid, tropical climate, it deteriorates and loses its value, doubtless accounting for some of the recorded failures of the drug. In this connexion I may note here that Dr. E. H. Hankin, of Agra, has sent me records showing great benefit in distemper of cats from the combined use of sodium morrhuate and distemper vaccine, but only fresh sodium morrhuate was of any use, and his observation has recently been confirmed as regards dog distemper by Mr. N. Chambers, F.R.C.V.S., to whom I am indebted for notes of three remarkable recoveries under this method of treatment.

The appearance of Dr. Boelke's paper led Dr. John Hume, of Perth, N.B., to report to me his four years' experience of sodium morrhuate, in from 0·5 to 1 c.cm. doses of the 3 per cent. solution with 0·5 per cent. phenol in rubber-capped bottles twice a week for six to eight months, the bottles being stood in warm water for a few minutes before use, when the solution should become clear. I hope his report will be published in full, but the following is a brief analysis of the salient points. Of 11 cases 3 advanced ones ended fatally after a few months to two years, but 7 of phthisis, including one with ulceration of the larynx and one with cavitation, and one of genito-urinary tuberculosis, all cleared up, losing active physical signs, temperature, and tubercle bacilli from the sputum or urine, and from 11 to 19 lb., with an average of 15 lb., were gained, and he concludes: "With sodium morrhuate the improvement is soon observed, and leads to a complete arrest of the disease in many early cases. It is a great help in advanced cases, but not so successful as in early ones. Patients do not require to be pressed to go on with the injections. They feel stronger and better with them and have a sense of well-being unobtainable by other methods."

TRIALS IN CASES NOT YIELDING TO SANATORIUM TREATMENT.

Thanks to the great kindness of several tuberculosis experts, I am able to report on short trials of sodium morrhuate in a few cases of phthisis not responding even to sanatorium treatment, a severe but necessary test to enable the limitations of the drug to be ascertained, and I wish to express my great indebtedness to all who have sent me reports.

With the kind permission of the Brompton staff, Dr. R. C. Wingfield reports on eight cases treated at the Frimley Sanatorium, only 1 of whom showed considerable improvement, 2 continued previous progress, 2 showed no change, and in 3 the disease continued to progress, and he concluded from this small trial that "the results are inconclusive and not very encouraging." Dr. T. N. Kelynack sent me a preliminary note by Dr. W. G. Kinton, medical superintendent of the Mount Vernon Hospital, reporting no definite reactions or harmful effects, and no change in the temperature curve definitely attributable to the treatment. The patients, with one exception, had improved in weight and general condition, but it was difficult to say how much was due to the drug and how much to general hygienic conditions. Hæmorrhagic cases were found to be least suitable, while "extensive moderately quiescent lesions with a tendency to fibrosis seem to have done well," but "a more extended experience is necessary before expressing a general opinion on its value." Dr. Marcus Paterson, of the Colindale Hospital for advanced pulmonary cases, reports 8 cases, 1 definitely improved while under treatment, 1 thinks he has improved, 3 stationary, 2 became worse (? cause), and 1 died while under treatment, probably due to the sodium morrhuate without the temperature being affected. A further report is promised later.

I am exceedingly indebted to Prof. Lyle Cummins for arranging the most extensive trial of sodium morrhuate in pulmonary tuberculosis yet undertaken through the medical officers of the King Edward VII. Welsh National Memorial Association for the Prevention, Treatment, and Abolition of Tuberculosis, and for sending me their reports, of which the following is a summary. Dr. H. A. Ross treated 11 cases, 3 improved, 5 not improved, and 3 worse, 1 much worse, and is uncertain whether the improvement in a few cases was psychic or not. Dr. R. Owen Morris has used the treatment in six advanced cases without any benefit, and in four moderately early cases with tubercle bacilli in their sputum, in two of whom it became negative under the treatment, but as they were doing well before he thinks they would have done equally well without the sodium morrhuate. Dr. D. A. Powell has treated three lung cases, which do not permit of any expression of opinion, and four surgical cases with definite improvement in two, and no change in the other two. Dr. D. W. Fenwick Jones treated 18 cases and found it harmless and of no benefit, and Dr. H. E. Watson in about eight cases, and found no definite effects from the drug. Thus no definite results have been obtained in the small series of cases of the above medical officers, but the two following reports relate to larger numbers and record some interesting experience. Dr. T. Williams has treated 30 cases for three months with results not different from hospital and hygienic treatment. Two chronic fibroid phthisis and one hilum case "made marked improvement after the first dose and have continued to make satisfactory progress," and one sinus cervical adenitis case "made very rapid improvement." Local reactions, occasionally followed by a rise of temperature, but not the malaise due to an overdose of tuberculin, were observed, but no increase of physical signs suggesting a focal reaction. With a clear light amber-coloured fresh solution general reactions can be avoided and the local reactions controlled and the treatment can be regarded as safe in all cases, and all tuberculous cases give a definite local reaction with 0·1 c.cm., but chronic bronchitis gave none with 1 c.cm., so it may have diagnostic value if other diseases produce none. He concludes: "In comparison with tuberculin treatment sodium morrhuate has the advantage in that the dose is easily determined by the local reaction, general reactions can be more easily avoided, are much less severe, and it can be used for cases where tuberculin is contra-indicated. The results are at least equal to those following tuberculin."

Dr. Charles Lloyd, of the Tuberculosis Institute, Lampeter, reports on a trial in about 140 cases, the most extensive I know of, including dispensary patients, and writes: "I find it difficult to give definite proof of the value of sodium morrhuate in the treatment of tuberculosis, still I feel confident that it does, in some way, assist the natural defensive mechanism." He found temperature reactions occurred very irregularly and were most evident in advanced or bad cases, and the pulse may be slower or unchanged, and he adds: "There is nothing very definite that one can point to, one way or the other, and one must rely on general impressions. I have given sodium morrhuate to about 140 cases, early, intermediate, and late, pulmonary and non-pulmonary. It has certainly failed in many cases of advanced disease, in the 'young adult type' and in cases with poor resistance, but I feel it has been of real help in many others." He proceeds to give notes of two cases which responded particularly well, including healing of laryngeal trouble, and states he has had several similar cases, and concludes: "I have found the preparation quite harmless in the doses recommended, but have never given more than 0·3 c.cm. to a bad case. It leaves much to be desired, but I must say it has given me better results than anything else I have yet tried."

The last report to reach me is from Dr. E. G. Fenton, of Limerick, who arranged for trials of sodium morrhuate in phthisis in February last, and sends notes of two bad cases treated by Dr. P. J. Holmes with remarkable improvement, and seven by Dr. A. Humphreys, mostly in dispensary practice, all of whom improved, two gaining 1½ st. in weight, once more showing that the drug can give good results in the absence of the advantages of sanatorium treatment.

SUMMARY OF TRIALS IN PULMONARY TUBERCULOSIS.

I have now summarised all the reports which have reached me of tests in phthisis, as far as possible quoting the conclusions of the experts, from which the following conclusions may be drawn. In the first place, the trials of sodium morrhuate in a few unfavourable cases, not improving in spite of sanatorium treatment, have not yielded any striking results, and they lend no support to Dr. Boelke's statement that "sodium morrhuate alone has given me the most uniformly successful results" in all forms and stages of tuberculous disease. Secondly, the cases recorded by Dr. Boelke and the reports of Drs. Hume, Lloyd, and Fenton prove that the drug is capable of effecting remarkable improvement, including complete disappearance of tubercle bacilli from the sputum, in a certain proportion of advanced cases, some of whom had resisted sanatorium treatment, while in earlier cases in dispensary and general practice very favourable results may be obtained by prolonged treatment for six months or more. Thirdly, small subcutaneous injections of clear freshly prepared solutions, the increase of the doses being regulated by the local reactions as described by Boelke, have proved uniformly safe in the hands of experienced workers, especial caution being used in hæmorrhagic and acute types of the disease. I therefore think that the method may now be safely used with advantage on a larger scale in tuberculosis dispensaries in the many early cases, who often have to wait for months before gaining admission to sanatoria; and I would also venture to suggest that sufficient evidence of possible benefit without material risk in early cases is now available to justify the trial of the drug in this class of case in sanatoria, in addition to the unfavourable ones hitherto almost exclusively selected for the trials, ample control cases being available for comparison whenever possible, the injections being continued twice a week for at least six months in doses not over 1 c.cm. in view of Dr. Hume's experience. If my contention is correct that sodium morrhuate induces the destruction of the tubercle bacilli in the body, as evidenced by the breaking up and disappearance of the organisms in the sputum, as it certainly does in the case of the lepra bacillus, its use should supplement in an important manner the building up of tissue resistance by sanatorium methods, and might quite possibly lessen the still lamentable proportion of recovered sanatorium cases, who succumb to the disease within a few years of their discharge from these very valuable institutions.

TRIALS OF SODIUM MORRHUATE IN SURGICAL TUBERCULOSIS.

Surgical tuberculosis cases present the advantage of allowing focal reactions at the site of the disease being more closely observed, so the following slightly abridged reports of the Carshalton and Fazakerley trials are of great interest, as they extended over more than a year and are being continued. Dr. Edna Mawson and Dr. Fry, in their reports from Carshalton, note that in seven cases new lesions developed while under treatment, nearly all tuberculous abscesses, and in three they "cleared up remarkably quickly when the treatment was stopped." Slight local reactions at the site of injection occurred in about one-third of the cases; focal reactions in the form of temporary increased discharge from sinuses were common during the first few weeks of treatment, but general febrile reactions were not met with. In a case of lupus a local application produced a violent inflammatory reaction, followed by rapid healing of three ulcers on the face. The majority of the patients increased in weight, even when no local improvement was noticed, and the general condition also improved in more than half the cases; but it is not possible to say how far this was due to the drug, although as most of the patients were under 16 it is considered doubtful if the psychological factor would enter in. A lasting decrease of the tuberculous lesions with sound healing resulted in about one-third of the cases, most marked in those with multiple superficial lesions or of the smaller joints, "but as these tend to do well it is difficult to judge the extent of the improvement due to the injections." Not much effect was produced in four cases of chronic lupus, and the results in sinus cases of long standing have been disappointing. (The frequency of secondary infections complicates this class of case.) The general conclusion arrived at is that "the improvement in about one-third of the cases treated suggests further trials."

Dr. C. Rundle, medical superintendent of the isolation hospital at Fazakerley, Liverpool, has kindly sent me a most valuable report on 24 cases of surgical tuberculosis, all febrile bed-fast cases, treated with sodium morrhuate with the help of Mr. J. T. Morrison and Dr. W. Crane, including disease of the spine, sacro-iliac, hip, knee, and elbow-joints, of ribs, tarsus, carpus, ulna, tibia, and radius bones, of glands, skin, and abdomen, and in 20 of them one or more discharging sinuses were present, while five had in addition pulmonary lesions with positive sputum. The only harm seen after a large number of injections was hæmoptysis and increased sputum with appearance of bacilli in it after an intravenous dose in a case of pulmonary tuberculosis (only subcutaneous doses are now being used), while one case of multiple bone lesions in a dying condition before treatment succumbed within three months, these being the only unfavourable results.

Local irritant reactions at the site of injection in the form of swelling, tenderness, and stiffness occurred in 60 per cent. of the cases after various doses and without any regularity. Focal reactions at the seat of disease were observed in 75 per cent., all those with pulmonary disease showing them in the form of increased harshness of the breath sounds, cough, and quantity of sputum passing off in 60 to 72 hours, and in all sinus cases as increased discharge, sometimes sanious, reaching its maximum in about 18 hours and passing off in 72 hours, while two genito-urinary cases had rigors and hæmaturia after injections. In 50 per cent. general reactions of varying intensity were observed in the form of headache, "cold in the head," general malaise, raised temperature, and rapid pulse. Immediate improvement following any general reaction was not sufficiently marked to be noteworthy.

RESULTS.

All the cases having been febrile, "30 per cent. of those treated have now normal or subnormal temperatures, 25 per cent. are still febrile and show no alteration in temperature, and the remainder (45 per cent.) are improving, but have not yet reached normal. Fifty per cent. of the cases show a decided improvement. In 20 per cent. there is some improvement. The remainder are in statu quo or worse. Fresh foci developed in 8 of the 24 cases treated. The occurrence of focal reactions, the development of fresh foci, and the changes occurring in the majority of the lesions, point to a specific action." All the cases had been under treatment for a considerable time, and Dr. Rundle adds that the treatment "should be used with extreme care where vital organs are concerned."

These important trials of sodium morrhuate in surgical tuberculosis, although still leaving much to be desired, are not without promise, and the officers of both institutions are anxious to continue and develop them. The results already obtained, and the important confirmation by the Fazakerley workers of my views that the drug has a specific action on tuberculous tissues, somewhat similar to that of tuberculin, the opinion of Dr. T. Williams that the preparation may safely be used in phthisis cases in which tuberculin is contra-indicated, together with the conclusion of Dr. Lloyd, from a unique experience of the drug in pulmonary tuberculosis, that it is both harmless and has yielded him better results than any other line of treatment, appear to me to fully confirm the statement I made in my first paper of February, 1919, that the results then obtained in India "justify me in bringing sodium morrhuate to the notice of the medical profession, to allow of the prolonged trials by many skilled workers which will be necessary before its permanent value, if any, can be decided, and the indications and contra-indications for its use worked out." That is still my position, and I only wish to add some suggestions for further lines of investigation, some of which are being undertaken by experts, who are already convinced that my methods are not without some promise of eventual greater success than at present.

Ethyl ester morrhuate is being tried on account of its greater stability and slower absorption than sodium morrhuate, which gets over the disadvantages of the instability and the necessity of making up fresh solutions of the latter, while the former is likely to produce less severe reactions; and Dr. Muir has recently reported to me that he found the ethyl ester more effective in tuberculous glands than the sodium salt.

Cod-liver oil intramuscularly, diluted with an equal quantity of pure olive oil to prevent pain, is also being tried, first, because it will retain vitamin A, which is absent from the morrhuates, and secondly, because there is some evidence that the oil itself has a definite injurious effect on tubercle bacilli in vitro, which is wanting in the morrhuates, indicating that some important substance is lost in the preparation of the latter. Thus, H. E. Kirschner, in a recent article [22] deploring the neglect of cod-liver oil in tuberculosis at the present day, states that it was a folk remedy for centuries, and has been used for a century past in tubercle of children, having a food value far in excess of other fat foods, because all but 14 per cent. of its fatty acids are in the easily absorbed and assimilated unsaturated form, and its vitamin fat-soluble A potency is 250 times that of butter, while it also aids absorption and deposition of calcium salts, which are deficient in tuberculosis and play an important part in the healing processes.

Effects of cod-liver oil on acid-fast bacilli in vitro were demonstrated in 1909 by Willian and Forsyth,[23] for when they were mixed and incubated at 37° C. for several months the organisms were rapidly decolorised by the carbol-fuchsin method, while recently H. B. Campbell and Jean Kieffer [24] have obtained very similar results, for freshly extracted cod-liver oil, added to glycerine potato medium on which tubercle bacilli were cultivated, rapidly inhibited the growth of the bacilli and led to their becoming granular, and, still more important, they lost their infectivity to guinea-pigs, although control tubes with cotton-seed oil in place of cod-liver oil only slightly retarded the growth.

The advantage of adding 10 per cent. creosote or 3 per cent. iodine as an antiseptic to ethyl hydnocarpates in the treatment of leprosy, as shown by Muir, suggests the trial of such additions to ethyl morrhuate in tuberculosis, in which both substances have been much used either orally or by inhalation, and other combinations of morrhuates with remedies with a reputation in tuberculosis will suggest themselves.

ALTERNATING SODIUM MORRHUATE AND TUBERCULIN INJECTIONS.

Lastly, I have long had in mind the possible advantages of combining tuberculin and morrhuate treatment on the lines by which Muir, at my suggestion, obtained beneficial results from using acid-fast bacillus vaccines with hydnocarpates in leprosy, for if by tuberculin injections an increase of the resisting powers of the patient to the toxins of the tubercle bacillus can be effected, it is quite possible that the subsequent use of morrhuates to break down that organism in the system may become both safer and more effective. During a visit to the Fazakerley Hospital a few months ago I had the privilege of discussing this and other questions with Dr. Rundle and his colleagues, since which they have been testing the suggestion, and have just reported that the alternate use of these two substances in a considerable number of cases suggests that it may prove to be a promising method, as indicated by the following three cases showing remarkable improvement.

"One had lesions in hip and rib, both with sinuses and abscesses in the soft tissues. In this case the sinuses and abscesses are healed, the temperature is subnormal, and there are no signs of active disease. It has to be stated that a portion of the rib was excised. The second had hip disease with several discharging sinuses; he developed a focus in the tibia; this was excised, as was also a focus which appeared in the sternum; he also got an abscess in the supraspinous fossa. In this case there is now only one small sinus at the hip with very scanty discharge. The discharge is lessening, and the sinus is contracting. The third case had extensive pulmonary disease, with cavitation and copious sputum; he had also an active focus in the spine. The pulmonary condition is very much improved, and the spine lesion is quiescent." Further results of this combination will be awaited with interest, as it appears to open up further possibilities of the useful application of the new methods.

CONCLUSION.

In conclusion, it is of interest to note that, while chaulmoogra oil derivatives have proved of great value in the treatment of leprosy, placing in our hands a far more effective means of dealing with that scourge than we formerly possessed; on the other hand, the morrhuates in small subcutaneous doses have proved both safer and more effective in tuberculous disease; confirming in a remarkable manner the century-old empirical opinions regarding both oils, just as our two great specifics for tropical disease are derived from cinchona bark and ipecacuanha root discovered by the aboriginal Indians of South America. The growth of medical science has vastly improved on the old empirical methods by furnishing us with soluble compounds of the active alkaloids quinine and emetine, the latter of which was, however, known to science nearly a century before I was fortunate enough to establish its great value in amœbic disease. In a similar way my Calcutta investigations have now demonstrated the value of the application of the same principle in obtaining the active portions of chaulmoogra oil in forms suitable for injection in leprosy, and those of cod-liver oil in tuberculosis; and I trust the evidence I have been able to bring forward to-day, thanks solely to the great kindness of a number of tuberculosis experts in testing my methods, to whom I cannot sufficiently express by obligations, will suffice to indicate possibilities of even greater advances through further research, a wide field for which has now been opened up. Invaluable as are the effects of sanatorium treatment, no one can doubt that the ultimate results still leave ample room for improvement, and perhaps we have been a little too much inclined to rest on our oars and to make insufficient efforts to find a more active and less costly remedy for the white man's scourge. If my attempts in this direction leads more tuberculosis experts to pursue this line of investigation, I am sanguine enough to hope that some real advance will accrue before very long, in which case my somewhat daring excursus into a field outside that in which my life's work has almost entirely lain hitherto, will be more than justified, and the investigations into the treatment of leprosy and tuberculosis, which occupied the last few years of my active service in India, may yet prove to be a contribution of some value to general medical science.

ON THE ANTIBACTERIAL POWER OF EGG-WHITE.

BY ALEXANDER FLEMING, F.R.C.S. ENG.,
DIRECTOR OF THE DEPARTMENT OF SYSTEMATIC BACTERIOLOGY, ST. MARY'S HOSPITAL;

AND

V. D. ALLISON, M.D. BELF.,
BEIT RESEARCH FELLOW.

(From the Laboratories of the Pathological Institute, St. Mary's Hospital.)

THE hen's egg forms one of the staple articles of our food. As it is marketed it does not reach the consumer until many days after it is laid, but if eggs from a shop window are examined bacteriologically it is found that, as a rule, they are sterile. Now, the contents of the egg are highly albuminous, and both white and yolk have been used in the laboratory, after being treated in various ways, as culture media for bacteria. It is clear, therefore, that ample foodstuff exists in the egg for the development of microbes, but in the ordinary course of events bacteria do not invade the egg for a long time after it is laid and exposed to infection. The question arises as to what is the protective mechanism which prevents infection. Our first thoughts run at once to the hard shell with which it is encased, and many experiments have been done on the permeability of the shell to infective bacteria.[1,2,3,4] Roughly it can be said as a result of these experiments that many bacteria can readily pass through the shell, although by mere mechanical means it delays the infection of the underlying contents of the egg.

Laschtschenko in 1909[5] and Rettger and Sperry in 1912[6] have shown that egg-white has antibacterial properties, so that when certain bacteria are planted into undiluted egg-white their numbers diminish, in some cases rapidly and in some cases slowly. These observers, however, did not clearly demonstrate the enormous potency of the antibacterial action of egg-white, nor was there any connexion made between this antibacterial action and the similar action of the tissues and secretions of fowls and other animals.

The authors[7,8,9] have shown that egg-white, in common with almost all the tissues and most of the secretions of the animal body, possesses the property of very rapidly dissolving a large proportion of the bacteria which are to be found in the air and with which the egg would be subject to infection. They have shown that this bacteriolytic power of egg-white is due to a ferment-like substance which they have termed "lysozyme," and that the lysozyme of egg-white is apparently identical with that of human tissues and secretions and even of vegetable tissues, for when a strain of a susceptible bacterium was made resistant to the lysozyme of egg-white by growing it in a very high dilution of this substance, it was quite as resistant to the lysozyme contained in any other tissue or secretion as it was to the lysozyme of egg-white. It would appear, therefore, that the bacteriolytic action of egg-white is a property not peculiar to this substance, but possessed by it in common with many other living substances and their products.

Action of Egg-white on a Susceptible Bacterium.

One of us (A. F.) isolated a large Gram-positive coccus which he called the *Micrococcus lysodeikticus*, on account of its usefulness in the demonstration of the lytic substance contained in the various tissues and secretions. When a thick suspension of this microbe in salt solution is mixed with a 1 per cent. egg-white solution, and the temperature of the fluid is kept about 50° C., there is complete clearing of the bacterial suspension in about 30 seconds and a microscopical examination of the fluid shows that the cocci have practically disappeared, being merely represented by a few "shadows" and many granules. The change is identical with that described and figured by the authors in connexion with the bacteriolytic power of tears. Again, if a drop of egg-white is placed on the surface of a culture plate which is covered with an opaque yellow sheet of growth of this microbe it will be seen that, where the egg has been superposed, the whole of the thick sheet of culture has been dissolved within one minute, if the temperature is kept at over 30° C. (The lytic action is slower as the temperature is reduced, exactly as we have shown with other secretions.) From these experiments it is obvious that the lytic action on a microbe, such as the *Micrococcus lysodeikticus*, which is very sensitive to lysozyme action, is a very powerful and rapid one, and this is further borne out when serial dilutions of egg-white are made in normal saline and to each dilution is added a measured quantity of this sensitive coccus. When these mixtures are incubated at 37° C. for 24 hours, it will be found that there will be evident lysis of the cocci in a dilution of the egg-white of 1 in 50,000,000. So far as a microbe of this type is concerned, therefore, the antiseptic action of egg-white is much stronger than that of any of the chemical antiseptics.

Bacteriolytic Power of Different Kinds of Egg-white.

Eggs which had not been laid more than a few days were obtained from the hen, thrush, wagtail, and moor-hen. The white from each of these was separated and the bacteriolytic power on the susceptible test microbe was estimated by making serial dilutions of each and adding to each dilution the same quantity of the test microbe. After incubation for one hour at 45° C., results were obtained which are shown in Table I.

TABLE I.—*Bacteriolytic Power of Egg-white from Different Species of Bird.*

Species of egg-white—	Lysis observed after one hour at 45° C. in a dilution of egg-white of 1 in (in thousands)—										
	2	4	8	16	32	64	128	256	512	1024	2048
Hen	+	+	+	+	+	+	AC	±	±	±	±
Thrush	+	+	+	±	Tr	0	0	0	0	0	0
Wagtail ..	+	+	AC	Tr	0	0	0	0	0	0	0
Moor-hen ..	+	+	±	Tr	0	0	0	0	0	0	0

+ = Complete lysis. ± = Partial. AC = Almost complete. Tr = Trace.

It will be seen from Table I. that there are marked differences in the lysozyme titre of the different species, the hen's egg white being much stronger than any of the others. Of course, it is possible that with a different test microbe the relative powers of these different eggs might be changed, but this experiment clearly shows that egg-white from different species of birds varies in its lytic power towards the same bacterium. The egg-white from a large number of hens' eggs, some brought direct from the country within two days of being laid and others bought in the shop nearest the laboratory, has been tested, and although there were slight differences in the bacteriolytic titre of different eggs, there was never any difference between two hens' eggs, comparable to that between hen's egg white and that of the other birds tested.

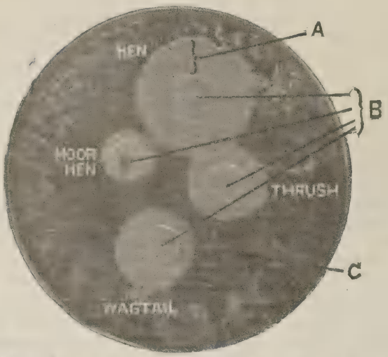
The same difference between the antibacterial power of hen's egg white and that of other birds can be demonstrated more dramatically in the following manner. An agar culture plate is taken and small portions of the agar are punched out, leaving holes into which are put equal quantities of the egg-white from different birds. These portions of egg-white are covered with several layers of agar, added, when liquid, at a temperature of about 50° C., each layer being allowed to solidify before the next is applied. In this way the egg-white is completely buried in the culture medium, and finally the whole surface of the culture plate is covered with a fresh layer of melted agar, and when this has solidified the surface is thickly planted with the *Micrococcus lysoideikticus* and the plate is incubated. The resultant growth is shown in Fig. 1, from which it will be seen that there is a definite area of complete inhibition of growth around the spots in which the different kinds of egg-white were embedded, but that the inhibitory area around the hen's egg white is much larger than that around the egg-white of any of the other birds tested. But it is not only the eggs of birds which have this lytic and inhibitory power on bacteria. The eggs of a fish (pike) were tested both by adding the eggs to a suspension of bacteria, which was promptly cleared, and by embedding the eggs in an agar plate the surface of which was subsequently planted with the coccus. In this latter case there was evident the same inhibitory zone, which was manifest in the case of the bird's egg white. (Fig. 2.)

The relative bactericidal action of hen's and duck's egg white was tested on a series of fæcal streptococci. Serial dilutions of the egg-white were made in normal saline solution, and 10 c.mm. of each of these dilutions were mixed with the same volume of a 1 in 1,000,000 dilution of a 24 hours' broth culture of the coccus, incubated for one hour at 37° C. and then planted out on agar. The resulting growth showed that there was a marked bactericidal action in every case, and that there was no essential difference between the bactericidal power of hen's and duck's egg white. As a rule, there appeared to be a more powerful bactericidal action of the hen's egg in the more concentrated solutions, but in the dilutions over 100 the lethal effect of the duck's egg appeared to be rather more marked.

Properties of the Bacteriolytic Substance.

The properties of the lysozyme in animal tissues and secretions, which is identical with that in egg-white, have already been described by us. It is not destroyed by drying, as is shown by the fact that commercial dried egg-albumin, which before it reaches the laboratory has in all probability been dried for many months, retains its bacteriolytic power to a marked degree. (Definite bacteriolysis of the coccus was observed after incubation for 18 hours at 45° C. in a dilution of the dried egg-albumin of 1 in 80,000,000.) From egg-white, also, the bacteriolytic agent can be precipitated by alcohol, and if this precipitate be removed and dried the lysin can be extracted from the precipitated proteins by normal salt solution. Little or none of the lytic agent appears to be destroyed by alcohol. The authors have shown that when pike's eggs are exposed to the action of various fluids, alcohol, ether, chloroform, xylol, and toluol, for several months their bacterio-inhibitory power is not altered.

FIG. 1.

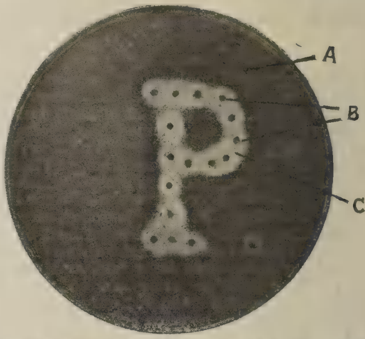


Inhibition of bacterial growth by egg-white from different species of birds. A, Zone of complete inhibition of growth. B, Egg-white embedded in agar. C, Opaque sheet of growth of *M. lysodeikticus*.

Antibacterial Power of Egg-yolk.

Rettger and Sperry[6] have stated that egg-yolk has no antibacterial power. When, however, it is tested on a very sensitive organism like the *Micrococcus lysodeikticus* which we have used, there is manifest a slight but definite bacterio-inhibitory, bactericidal, and bacteriolytic power. If some of the egg-yolk is embedded in an agar plate and the surface planted with *M. lysodeikticus*, it is found that there is no growth of the coccus immediately over the yolk, but the very large area of inhibition which is so striking when egg-white is used is not here reproduced. By explanting experiments it can be clearly demonstrated that some bactericidal action takes place, and by microscopic examination of the cocci after they have been acted on by egg-yolk it can be seen that there has been a definite lytic action.

FIG. 2.



Inhibition of bacterial growth by eggs of a pike. A, Opaque sheet of growth of *M. lysodeikticus*. B, Pike's eggs embedded in agar. C, Zone of complete inhibition of growth.

Does Egg-yolk Interfere with the Bactericidal Action of Egg-white?

This was tested on a very sensitive organism (*M. lysodeikticus*), and it was found that the antibacterial power of egg-white was not interfered with when it was mixed with an equal volume of the yolk. When, however, the bactericidal power was tested to a less sensitive organism, *Streptococcus fæcalis*, quite a different result was obtained. One volume of egg-white was mixed with one volume of a suspension of streptococci, and to a similar mixture one volume of the yolk was added. After incubation for one hour these two mixtures were plated out on agar along with one volume of the coccal suspension (to show the number of cocci implanted in the egg mixtures) when it was found that the egg-white alone destroyed almost all the cocci, but when the yolk had been added there was little or no bactericidal power manifest. This result agrees with the findings of Rettger and Sperry.[6]

It would appear, therefore, that where a very susceptible microbe is concerned the yolk has in itself some bactericidal power and it does not interfere with the antibacterial action of the white, but when the test microbe is less susceptible, the yolk has a definite inhibitory action on the bactericidal power of the white.

Action of Egg-white on Different Types of Micro-organisms.

The inhibitory action of egg-white on the growth of air-borne bacteria can readily be shown by taking two agar plates, coating one of them with a thin layer of egg-white, and exposing them to the air of the laboratory for an hour, after which they are incubated. It will be found that on the control plate there are very many colonies of a great variety of microbes, whereas on the plate which was coated with egg only a few colonies develop, and almost all of these are moulds and not bacteria.

The bacteriolytic power on the common air-borne bacteria was tested by making suspensions of 100 strains of such bacteria isolated haphazard, adding to these an equal volume of a 1 per cent. solution of egg-white and incubating at 45° C. The lysis was noted by the partial or complete clearing of the opaque bacterial suspension. It was found that after 24 hours' incubation there was evidence of lysis in 75 of the 100 bacteria tested. Some strains of bacteria were completely dissolved in a few minutes, while others were only partially dissolved after 24 hours. The inhibitory and lytic action of egg-white on air-borne bacteria probably explains the fact that egg-white exposed to the air remains for a long time uncontaminated. The antibacterial action of egg-white was investigated also as regards bacteria isolated from the human body.

The bacteriolytic power was tested by mixing equal parts of suspensions of the various bacteria with dilutions of egg-white and incubating the mixtures at 45° to 50° C., after which it was noted whether the suspension had cleared. The results obtained are set forth in Table II.

TABLE II.—*Bacteriolytic Action of Egg-white on Organisms Derived from the Human Body.*

Microbe tested.	Dilution of egg-white used.	Bacteriolysis observed.
Staphylococcus	1 in 100	Partial or none.
Streptococcus pyogenes ..	,,	Trace or none.
,, *fæcalis* ..	,,	Complete or partial.
Pneumococcus	1 in 10	None or a mere trace.

B. diphtheriæ	1 in 10	Partial.
B. hoffmannii	,,	None.
B. acidophilus (of mouth)	,,	,,
Streptococcus mutans ..	,,	Partial.

Bactericidal experiments were also carried out. Suitable dilutions of broth cultures of the organisms were made and mixed with equal volumes of serial dilutions of egg-white. After incubation for one hour at 37° C. these mixtures were plated out on agar. It was found that egg-white had a marked bactericidal power on staphylococcus, *Streptococcus fæcalis*, and *B. coli*, while a definite but less powerful action was manifest on *B. typhosus*, the paratyphoid bacilli, and the cholera vibrio. The results are shown in Table III.

TABLE III.—*Bactericidal Action of Egg-white on Some Pathogenic Organisms.*

Test organism.	Number of colonies obtained after treatment of the bacterium with egg-white in a dilution of 1 in—							
	2	4	8	16	32	64	128	Control.
Staphylococcus	17	19	50	48	72	165	254	271

B. dysenteriæ (Flexner)	62	60	71	64	74	71	68	72
B. pestis	54	57	61	51	62	63	59	60

As the bactericidal action of egg-white on some of these organisms was not very powerful, experiments were carried out to see if any bacterio-inhibitory power was present. Two series of tubes were prepared, one containing 0·5 c.cm. broth, 0·1 c.cm. egg-white, and 0·5 c.cm. of a 1 in 1,000,000 dilution of a broth culture of the test organism, and the other 0·6 c.cm. broth and the same amount of the bacterial culture. After three and six hours' incubation at 37° C. 20 c.mm. from each of the tubes was planted out on agar plates and the colonies counted. The organisms tested were *Staphylococcus aureus*, *Streptococcus pyogenes*, *B. coli*, *B. anthracis*, and *B. typhosus*, and it was found that there was marked inhibition of growth in every case.

The bacteriolytic action on *B. coli* was tested on 12 strains, some hæmolytic and the others non-hæmolytic. After incubation for 18 hours in a 1 in 10 dilution of egg-white it was found that in three cases there was almost complete clearing of a thick suspension of the bacilli, and with six other strains there was a partial clearing, while there was no apparent change with three strains. There appeared to be no difference in respect of their susceptibility to lysis between the hæmolytic and the non-hæmolytic varieties of *B. coli*.

The antibacterial action of egg-white on the streptococcal group calls for special comment. The bacteriolytic action of a 1 in 10 solution of egg-white was tested on 80 strains of streptococci of various types isolated from sputum, naso-pharynx, urine, and fæces, and it was found that all the strains were to some extent susceptible to the lytic action of the egg-white, the results obtained varying from a partial clearing of the suspension to absolute clarification and disappearance of the organisms.

The action of egg-white was also tested on a large number of strains of *Streptococcus fæcalis*. Preliminary experiments had shown that this organism, which is remarkably resistant to many adverse influences such as heat and drying, was comparatively readily dissolved by the lysozyme contained in egg-white. Sixteen strains which had been proved by cultural and serological methods to be *Streptococcus fæcalis* were grown on agar, suspensions of the cocci were made in saline, and to these suspensions were added equal volumes of a 2 per cent. solution of egg-white. After six hours' incubation at 45° C. there was an almost complete clearing of the streptococcal suspensions. Many other strains have since been tested, and the result has been the same in every case.

The susceptibility of some of the fæcal organisms, and especially of the fæcal streptococci, to the bacteriolytic action of egg-white led to an investigation as to whether egg-white taken by the mouth would have any effect on the streptococci of the intestine. It was first necessary, however, to determine whether the lysozyme of egg-white would survive peptic and tryptic digestion.

Effect of Peptic Digestion on the Lysozyme of Egg-white.

Two mixtures were made as follows :—

1. Egg-white, 1 in 1000, 3 c.cm. +0·25 c.cm. normal saline.
2. Egg-white, 1 in 1000, 3 c.cm. +Pepsin (1 in 10) 0·1 c.cm. +HCl (n/20) 0·15 c.cm.

These were incubated at 37° C. to allow of the digestion of the egg-white in tubes which contained the complete digestive mixture. After two hours, when the digestion appeared to be complete, the contents of tube 2 were neutralised with n/20 NaOH and the volumes were equalised; the contents were then titrated for the presence of lysozyme by making serial dilutions, and adding to each of these a measured quantity of the test coccus (*M. lysodeikticus*). The results obtained showed that peptic digestion had not diminished the bacteriolytic power.

Effect of Tryptic Digestion on Lysozyme.

This was tested in the same way as was peptic digestion. Tubes were put up containing active trypsin and trypsin which had been rendered inert by boiling. The digestion of the egg-white was considered complete when there ceased to be any clouding of the test mixture on boiling. On titrating the digested egg-white for lysozyme it was found that it gave the same titre as the control tubes, which contained egg-white incubated with saline solution and inactivated trypsin. It was evident, therefore, that tryptic digestion had no effect on the lysozyme contained in egg-white.

Effect of the Ingestion of Egg-white on the Streptococcal Content of the Fæces.

An individual was chosen for this experiment whose fæces had been examined many times and always showed a large preponderance of streptococci in the cultures. Cultures of the fæces were made daily on blood-agar plates, and the relative number of streptococci and *B. coli* were counted. From the fourth to the twelfth day of the experiment the white of four hen's eggs was taken, two in the morning two hours before breakfast and two at night four hours after the last meal. The results obtained are shown in Table IV.

TABLE IV.—*Effect of the Ingestion of Egg-white on the Intestinal Flora.*

Day of expt.	No. of colonies counted.		Relative No. of colonies.		Day of expt.	No. of colonies counted.		Relative No. of colonies.	
	B.c.	St.	*B.c.*	St.		*B.c.*	St.	*B.c.*	St.
1	62	419	1	7	10*	733	120	6	1
2	37	485	1	12	11*	363	88	4	1

7*	615	52	12	1	16	115	675	1	6
8*	622	198	3	1	17	36	644	1	18
9*	120	114	1	1	18	52	554	1	11

B.c. = *B. coli*. St. = Streptococci.
* Indicates the days on which egg-white was taken.

It will be seen that following the ingestion of the egg-white there was a very considerable change in the relative numbers of *B. coli* and streptococci, the latter diminishing very markedly in proportion. This change, however, seemed to be maintained only for nine days, when the condition returned to its original state.

It is possible that it was merely the addition of so much proteid to the diet which affected the flora, but it is probable that part, at least, of the change was due to the antibacterial action of the egg-white on the streptococci. The fæces were tested daily for lysozyme by drying them with acetone (which does not destroy lysozyme), and then adding a pellet of the dried fæces to a suspension of our sensitive test organism (*M. lysodeikticus*). The fæces from the third day to the end of the experiment contained a lytic substance to this organism, although before the ingestion of egg-white repeated examinations had failed to reveal the presence of any lytic substance.

It was thought that possibly a strain of streptococci had developed in the intestine which was resistant to the lysozyme of egg-white, but tests made on the streptococci isolated at the end of the experiment showed that they were all capable of being dissolved by egg-white. The tests were, however, not very accurately quantitative, and as the authors have shown it is quite easy to develop strains of bacteria resistant to the lytic action of egg-white and other lysozyme-containing substances by growing them for 24 hours only in the presence of a small amount of lysozyme, it is very probable that strains of streptococci developed which were slightly more resistant to the lytic action of the egg-white and so were able to propagate themselves freely even in the presence of a small amount of lysozyme in the intestine.

Clinically we have recommended the ingestion of egg-white to a considerable number of patients who had a large number of streptococci in the fæces and who suffered from feelings of lassitude, headache, &c., which so often accompany a streptococcal intestinal flora. In most cases they have reported a very definite temporary improvement in their symptoms. This may, of course, have been merely a psychological effect, or it may have been a temporary action on the streptococci.

Antiseptic Action of Egg-white in Blood.

The antiseptic action of egg-white in blood was tested in the same manner that one of us (A. F.)[10] has described in connexion with chemical antiseptics. It was found that whereas egg-white, in marked contrast to the chemical antiseptics, has no destructive effect on the leucocytes, it has considerable inhibitory or lethal effect on some of the bacteria. Egg-white, mixed with blood so that the resulting concentration is 1 per cent. of egg-white, will completely inhibit the growth of *Streptococcus fæcalis*, and allow of only a very scanty development of organisms like staphylococci and *B. diphtheriæ*.

The fact that egg-white mixed with blood has definite antibacterial properties led us to investigate the result of injecting this substance into the circulation. A rabbit weighing 2970 g. was injected intravenously with 20 c.cm. of a 10 per cent. solution of egg-white (equal to 2 c.cm. of undiluted egg-white). No ill-effects followed the injection. Blood was taken from the rabbit before and at intervals after the injection, and the serum was titrated for bacteriolytic power to our test coccus. The results are shown in Table V.

TABLE V.—*Lysozyme Content of Rabbit's Blood Serum After Intravenous Injection of 20 c.cm. of 10 per cent. Egg-white.*

Time blood sample taken.	Dilution of serum in which complete lysis of the cocci was observed after 1 hour's incubation at 45° C.
Before injection	Not complete in undiluted serum.
Immediately after injection ..	1 in 600
5 minutes ,, ,, ..	1 ,, 400
15 ,, ,, ,, ..	1 ,, 200
30 ,, ,, ,, ..	1 ,, 80
1 hour ,, ,, ..	1 ,, 50
2 ,, ,, ,, ..	1 ,, 40
3 ,, ,, ,, ..	1 ,, 10

Egg-white solution when titrated gave complete lysis in 1 in 64,000. If we assume that the total blood content of the rabbit was 1/13th of its body-weight, this would give us a blood volume of 228 c.cm. The amount of egg-white injected, therefore, would give a concentration in the rabbit's blood of 1 in 114. Now, the bacteriolytic titre of the serum immediately after injection was 1 in 600, which, when multiplied by the dilution of egg-white in the blood, represents a dilution in the rabbit of the egg-white injected of 1 in 68,400. This closely corresponds with the bacteriolytic titre of the egg-white, which was found to be 1 in 64,000. It is evident, therefore, that for a short time the bacteriolytic power of the egg-white injected into the rabbit is maintained at its full strength. After about 15 minutes it is reduced to about one-third, but even three hours after the injection the rabbit's blood serum has a very definitely increased antibacterial power.

No ill-effects followed the injection into the rabbit of sufficient egg-white (suitably diluted) to make in the blood a concentration of almost 1 per cent., and it is possible that in cases of a generalised infection with a microbe susceptible to the bacteriolytic action of egg-white—e.g., *Streptococcus fæcalis*—the intravenous injection of a solution of egg-white might be beneficial.

Summary.

Egg-white contains a bacteriolytic, bactericidal, and bacterio-inhibitory substance. On a susceptible bacterium the lytic power is still manifest when the egg-white is diluted 50,000,000 times. The bacteriolytic power of egg-white from different species of birds varies considerably when tested to the same microbe. The egg-yolk has a very slight antibacterial action on a susceptible organism, but when tested to a less suceptible microbe it has apparently no antibacterial power, and to some extent inhibits the bactericidal action of the egg-white. Egg-white inhibits the growth of most of the pathogenic bacteria tested, and has a definite lethal or lytic effect on many of these bacteria—e.g., staphylococcus, streptococcus, meningococcus, *B. typhosus*, *B. anthracis*, &c. The lysozyme of egg-white resists peptic and tryptic digestion, and following the ingestion of raw egg-white by the mouth the number of streptococci in the fæces was temporarily much reduced. Egg-white added to blood in vitro maintains its antibacterial action, and when injected intravenously into an animal it confers on the blood serum of the animal marked antibacterial powers which are still evident after several hours.

THE FACIAL PHENOMENON IN OLDER CHILDREN.

BY STANLEY G. GRAHAM, M.B. TORONTO,
AND
GRACE H. ANDERSON, M.D. GLASG.
(From the Royal Hospital for Sick Children, Glasgow.)

IN 1860 Trousseau first called attention to the fact that laryngismus, carpo-pedal spasm, and convulsions were all manifestations of one condition—namely, tetany. It was not until 1879, however, that Chvostek described the sign which bears his name. Chvostek's sign, or the facial phenomenon, is a contraction of the facial muscles elicited by tapping the branches of the facial nerve, and has generally been accepted as an indication of the presence of tetany in infants. It has, however, been observed to occur in older children in many other diseases, such as spastic diplegia, epilepsy, tuberculosis, and gastro-enteritis. Most observers have merely commented on the fact that the sign is present in these conditions and have offered no explanation as to its possible significance.

While making a study of tetany during the past year, we have been struck with the frequency with which this phenomenon occurred in older children who showed no other sign of tetany and from whom no history of previous tetany could be elicited. The question as to whether increased mechanical excitability, manifesting itself in the form of a Chvostek's sign, is to be regarded as a phenomenon of clinical significance has therefore arisen. In an attempt to throw some light on this problem we have examined healthy children under different conditions as well as those in hospital wards or attending dispensary for ailments other than tetany.

Since we wished in the first instance to come to a decision as to the possibility of a connexion between the facial phenomenon and tetany in the older child, we have selected the material for investigation from three different sources. The first group consists of children attending a school in one of the poorest districts where rickets and tetany are common. The second group was from a school in a better working-class district, where one would expect tetany to occur more rarely. Children of the third group were attending a private school in one of the best residential districts of the city in which tetany is almost unknown. In addition we have recorded the occurrence of the facial phenomenon (F.P.) in children attending the out-patient department of the hospital. Chvostek's sign was considered positive when on tapping the cheek a contraction of the muscles was observed at the forehead, at the angle of the nose, or at the mouth. A contraction at all three places we recorded as + + +, and at one place only as +.

It should be noted here that a marked mouth twitch was frequently obtained in the absence of any contraction at the brow or nose. Further, although in many cases very marked contractions occurred at all three places the mouth twitch was usually the most notable. On the other hand, in infants and young children with other signs of manifest tetany, it has been our experience that the brow twitch is usually the most severe of the three, and that only when this contraction is marked does one get a mouth twitch as well. The sudden rapid twitch obtained at the lip in these cases is not to be confused with the slower and more sustained "sucking reflex" elicited in the normal sleeping infant by tapping or stroking the cheek.

Attention may also be called to the fact that in the older child the facial phenomenon may vary from day to day. This variation cannot be correlated with any obvious change in the general condition of the child, and has also been observed by Mosse[1] and Hölzel.[2] The Chvostek sign in children with undoubted tetany, on the contrary, remains singularly constant except after a convulsion, when it is frequently not elicited, or during treatment, when it disappears gradually, the brow twitch being usually last to go.

Table I. shows in detail the figures obtained from our investigation :—

TABLE I.

—	No. of cases examined.	Sex.	No. showing positive F.P.	Per cent. of positive F.P.
(*a*) Children from poor class school	266	Boys	65	24·4
	301	Girls	77	25·5
(*b*) Children from better working-class school	351	Boys	107	30·5
	508	Girls	158	31·1
(*c*) Children attending private school ..	144	Girls	55	48·2
(*d*) Children attending dispensary	72	Boys	13	18·0
	81	Girls	23	28·1
Total	1723		498	29·0

In all 1723 individuals between the ages of 3 and 18 years of age were examined, the majority of them being between 5 and 12 years. In 498, or 29·0 per cent. of these, we obtained a positive facial phenomenon. In each of the groups of healthy children the percentage occurrence of the sign in boys and girls is almost equal, though the very small differences which exist indicate a slightly greater frequency in the case of the girls. In the children seen at the out-patient department the sign was found much more frequently in the girls, though the smaller numbers included in this group render the figures less reliable.

The most striking fact elicited from the figures is that the Chvostek sign occurred most frequently amongst the healthy children of the best district, and least frequently amongst the children of the poorest class. This supports the view that the sign in older children is not an indication of latent tetany. Rickets is a disease which is almost entirely limited to the poorer classes in this city, and it is well known that the incidence of tetany bears a close relationship to that of rickets. Hence, if the facial phenomenon is to be taken as an indication of latent tetany, one would expect to find it more frequently in the poorer than in the better class districts. This, however, is far from being the case.

Amongst the dispensary cases the facial phenomenon not only occurred less frequently than amongst the healthy children, but appeared to bear no relationship to any of the pathological conditions for which the children were attending, since its frequency in any one disease was not sufficiently striking to call for attention.

We have further examined a certain number of the children showing a positive facial phenomenon for other signs of tetany but were unable to find them. In Table II. we have collected the results of a more detailed study of 12 of those who were in the hospital wards. The electrical reactions alone were determined in 20 others, but as the results were similar to those recorded in the table, they have been omitted for the sake of brevity.

From a study of Table II. it will be apparent that in no case did the electrical reactions afford conclusive evidence in favour of a diagnosis of tetany. A kathodal opening contraction was never obtained with a current less than 5 ma. The kathodal closing contraction varied between 0·3 ma. and 1·0 ma., and bore no relationship to the severity of the facial phenomenon. In six of the cases we found "anodal irritability"—that is, an anodal opening contraction was obtained

with less current than an anodal closing contraction. This sign has been suggested by von Pirquet [3] and others as an indication of the existence of latent tetany. We ourselves have quite frequently obtained an anodal opening contraction with less current than the anodal closing contraction in normal children with no facial phenomenon and no history suggestive of tetany, while Findlay, Noel Paton, and Sharpe[10] have pointed out that this so-called "anodal irritability" may occur in normal animals. Indeed, we have seen it present on one occasion and not on another in the same apparently healthy child. We do not therefore attach any importance to its occurrence. It has, in fact, been our experience that in doubtful cases of latent tetany little help in substantiating the diagnosis is to be gained from a study of the electrical reactions.

TABLE II.—*Giving Electrical Reactions and Content of Serum in Calcium and Phosphorus.*

Sex.	Age in years.	F.P.	Disease.	KCC.	ACC.	AOC.	KOC.	KCT.	Ca.	P.
Girl	4	+ + +	Post-diphtheritic paralysis.	0·5	1·3	2·4	5 +	2·0	10·2	3·2
,,	8	+ + +	Cerebral tumour.	0·3	1·2	0·6	5 +	1·5	10·5	5·8
,,	8	+ + +	Rheumatism.	0·8	2·0	1·6	5 +	2·2	12·0	5·1
Boy	5	+ + +	Epilepsy.	0·4	1·6	1·4	5 +	2·0	10·5	5·2
Girl	6	+ + +	Cerebral tumour.	0·4	1·0	5 +	5 +	1·6	11·4	5·0
Boy	6	+ + +	Epilepsy.	1·0	1·8	3·2	5 +	4·0	10·4	5·7
Girl	13	+	Tuberculosis.	0·7	1·0	5 +	5 +	2·2	10·5	4·0
,,	12	+ +	Encephalitis lethargica.	0·3	1·1	1·1	5 +	2·5	10·5	6·4
Boy	11	+ + +	Epilepsy.	0·6	1·8	1·6	5 +	4·0	11·4	5·1
Girl	8	+ + +	,,	0·8	2·0	1·6	5 +	2·2	12·0	5·1

It is also of importance to note that the calcium and phosphorus content of the serum was essentially normal in all the cases examined, and we have found that the facial phenomenon does not completely disappear under treatment by calcium chloride in these cases as it invariably does in latent tetany.

We have also examined 320 infants under 3 years of age in the out-patient department of the hospital and found in this group 46, or 14·3 per cent., of positive Chvostek signs. The figures for this group in detail are as follows:—

Boys examined ..	161 ..	positive	22 (13·6 per cent.)
Girls ,, ..	159 ..	,,	24 (15·0 ,, ,,)

Practically all of the cases with a positive sign in this group were undoubtedly suffering from tetany in either a latent or an active form. The presence of other indisputable signs at the time of examination, or a history of convulsions, carpo-pedal spasm, or "crowing" could be readily elicited.

Discussion.

Thiemich [4] and Herbst [5] have both stated that a positive Chvostek's sign justifies a diagnosis of latent tetany. Schultze [6] examined 1648 school-children between the ages of 6 and 14 years, and found Chvostek's sign positive in 8·4 per cent. He also found increased electrical excitability in 58 per cent. of those showing a positive sign, and in the remaining 42 per cent. there was a history of convulsions in the child or convulsions in some other member of the family. We cannot determine on what grounds he diagnosed increased electrical excitability, but of course if he considers anodal irritability as evidence of this his figures are readily explainable. Veronese [7] tested 413 children for the presence of a facial phenomenon and found it in 21 per cent. The children examined were between the ages of 5 and 9 years. Pollitzer [8] found a positive sign in 78·2 per cent. of rachitic children, and 18·4 per cent. of other children. He comments on the surprising frequency with which the sign occurs in tuberculous cases free of rachitic complication, and suggests that the demineralisation which is common in tuberculosis may be responsible for the mechanical over-excitability. Hölzel,[2] in 2314 patients suffering from various types of insanity, found a positive Chvostek sign in 17·7 per cent. of males and 22·4 per cent. of females. It was not constant from day to day and was seldom seen in patients over 40 years of age. Römer [9] states that a positive facial phenomenon was obtained in 16 per cent. of epileptics. He also found increased electrical excitability in these cases, and advises that they be treated with calcium. We have examined 85 epileptics of all ages and found the incidence less than in any of the groups of healthy children. Our figures are as follows:—

Males examined ..	61 ..	positive	7 (11·5 per cent.)
Females ,, ..	24 ..	,,	6 (25·0 ,, ,,)
	85		13 (15·3 ,, ,,)

Mosse [1] frequently found the Chvostek sign in older children, but concluded that it has not the same significance in the older child that it has in infants and young children.

While it is evident from the figures of the above investigators that the facial phenomenon is frequently associated with diseases other than tetany, our results show that the incidence of the sign is just as great amongst apparently healthy individuals, and for this reason we would hesitate to attach any clinical significance to its occurrence in the older child. The fact that the phenomenon was found most frequently in children living under the best social conditions is, however, difficult to explain. The highly-strung, neurotic type of child is perhaps more commonly encountered in this class than in any other, and it seems probable that the exaggerated response to the sudden mechanical stimulus is merely an indication of this increased nervous tension.

Conclusions.

1. In 1723 children between the ages of 5 and 18 years, 29·0 per cent. showed a positive facial phenomenon.

2. A positive facial phenomenon in older children is not to be considered as evidence of latent tetany, because (*a*) there is no increased electrical excitability; (*b*) no other sign of tetany and no history of previous tetany could be obtained in any of the cases; (*c*) the sign varies from day to day; (*d*) the calcium and phosphorus content of the serum were found to be altered; (*e*) the sign was found most frequently amongst a class of children in whom tetany rarely occurs; (*f*) treatment with calcium chloride failed to produce a complete disappearance of the sign, as it does in cases of undoubted tetany.

3. The fact that the sign occurred as frequently amongst healthy as amongst ailing children, and its common occurrence in the children brought up under the best social conditions, have led us to attach little significance to its presence except as a possible indication of a neurotic disposition.

We desire to express our gratitude to Dr. Leonard Findlay for much help and interest in the investigation.

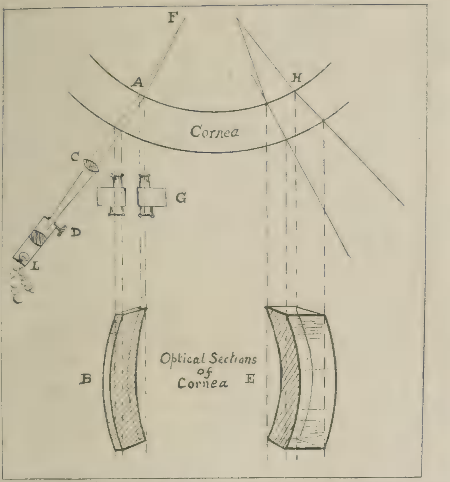
GULLSTRAND'S SLIT-LAMP IN THE OUT-PATIENT WORK OF AN EYE HOSPITAL.

BY LEWIS H. SAVIN, M.R.C.S. ENG.

THE principle of Gullstrand's slit-lamp is in its essence a very simple thing. A fine flat wedge-shaped beam of light is thrown obliquely across the cornea (Fig. 1, A). Looking from in front with a binocular microscope (G) one can see lit up an oblique section through the corneal substance as in (B). The tip of this light wedge is the image (F) cast from the lamp (L) by a lens (C) of an illuminated slit (D). Widen your slit and you produce a broader wedge (H), and instead of the fine optical section with its delicately illuminated corneal nerves, a good deal of the anterior epithelium and Descemet's membrane is also lit up in the form of a truncated pyramid (E). The rest of the slit-lamp is an ingenious mechanism for directing the beam of light so that, for instance, it may be made to pass across the anterior chamber and the lens.

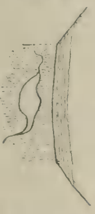
FIG. 1.



Diagrammatic schema of slit-lamp (not drawn to scale). For this the author is indebted to Dr. J. Keyms.

On the front of the cornea it is very striking to watch the continuous stream of tears passing across, resembling water across a West-End florist's windows. The iris is an exquisite living spongework continually dilating and contracting, a beautiful sight, especially in light-grey eyes. Darker irides have a coarser texture. Throwing the beam through the lens it is interesting to examine posterior polar opacities, if present, which they often are. Tiny egg-shaped patches in the posterior capsule (Fig. 2), they often have thread-like processes, remnants, one supposes, of the tunica vasculosa lentis.

FIG. 2.

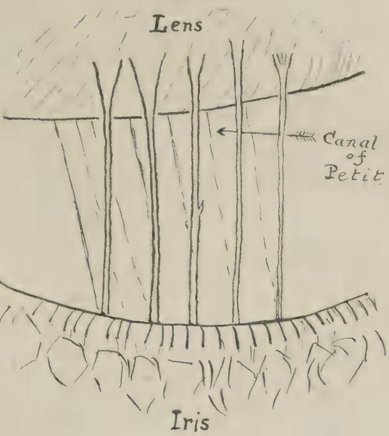


Posterior capsular lens opacity seen by diffuse light.

I have once seen the suspensory ligament of the lens in the living eye. A small boy had congenitally dislocated lenses, on one of which a discission had been performed before he was examined. In the other eye the suspensory ligament was plainly seen, rounded fibres passing in front and behind the lens, leaving the canal of Petit plainly visible (Fig. 3). Where the discission had been performed in the other eye it was interesting to see the swollen lens substance, cloud-like masses protruding through the incisions in the lens capsule.

In the ordinary Gullstrand model the light beam need not necessarily be white, but can be converted by a suitable adjustment to red-free light. Then the fine red blood-vessels stand out black, and it is possible with difficulty to watch the blood circulating through a vessel, the short black columns of the blood passing steadily along. In this way it is possible to determine the velocity of the blood, and pharmacologists may study directly the effect of drugs on the capillaries.

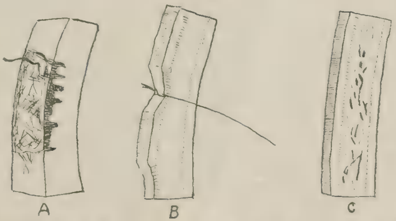
FIG. 3.



Showing suspensory ligament of lens.

Supposing a man comes up with a faint nebula of the cornea. Has it been formed by an ulcer, an interstitial keratitis, or what? The slit-lamp throws considerable light on the question. The ulcer leaves its scar on the surface, Fig. 4 (A) (B), the keratitis in the corneal substance (C), and with the slit-lamp it is possible to determine absolutely the level of any scar tissue.

FIG. 4.

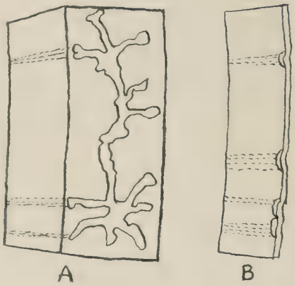


Corneal opacities. A. Nebula after ulcer. B. Healed ulcer. C. Nebula from tuberculous interstitial keratitis.

How is a corneal ulcer progressing? Besides allowing you to see the ulcer illuminated at many times its natural size, by viewing the ulcer in optical section you can easily see how far it has eaten its way into the corneal substance. For instance, the dendritic ulcer in Fig. 5 can be seen beautifully outlined in fluorescein (A), while the optical section (B) shows that the ulcer is entirely superficial. When an ulcer is stained with fluorescein the dye penetrates some little way into the substantia propria of the cornea. The lines passing across the optical section (B) are lines of shadow from the fluorescein-coloured areas.

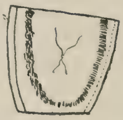
Every clinician knows the difficulty which sometimes attends the distinction between a primary and secondary glaucoma. In this the slit-lamp often shows itself of value, as it will often show the presence of very fine spots of keratitis punctata on the posterior surface of the cornea. In a primary glaucoma, when the anterior epithelium is focused up, cloudy patches can be seen studded with vesicles. In between the cloudy patches are often clear lanes of normal epithelium lit up by diffuse light. The posterior epithelium is clear. In secondary glaucoma, in addition to the cloudy anterior, epithelium K.P. can often be seen on the posterior surface. Anomalies of shape in the cornea, such as kerato-conus, are readily demonstrated. An important field for the lamp lies in the study of lental opacities. Their exact position can be found, and it can be easily seen in a cataract before operation just how much clear lens matter still remains, so that the operator can choose the best possible time for removal.

FIG. 5.



A. Dendritic ulcer stained with fluorescein.
B. Optical section of A.

FIG. 6.



Section of lamellar cataract.

Lamellar cataracts form an interesting study (Fig. 6). The relative position of the opaque layers of lens varies in different cataracts. As the lens grows in size by proliferation of the cells at the equator, one may suppose that the lamellars, with more superficial opaque layers, are of later formation than the deeper cataracts. With more material for judgment it may become possible to give an approximate date to the period of malnutrition which formed the cataract.

I have already mentioned the exquisite activity of the iris as seen under the slit-lamp—for instance, in a case of old iritis with a few posterior synechiæ. These tough, thin bands jerk taut as the iris tries to dilate, much like a rope on a flapping sail. Early blurring of the iris spongework and pigment patches on the lens are to be seen much better than with an ordinary binocular loupe. Sometimes a chronic uveitis can be detected long before ordinary methods would permit. A woman complained that one eye seemed slightly misty. Vision was 6/9, 6/5 in the other eye. The iris was a slightly paler blue than its companion, but dilated freely under a mydriatic. There was no appreciable refractive error. Why did the woman only see 6/9? Examination with a loupe showed a few fine specks on the back of the cornea. The slit-lamp showed these specks were definite patches of K.P. It was a chronic uveitis. When the anterior vitreous humour was lit up by the light wedge, myriads of minute opacities could be seen passing across the field of view on movement of the eye, just like snowflakes carried by the wind. In a case of sympathetic ophthalmia the slit-lamp showed opacities five days before any other signs were seen.

It is always possible to detect vitreous opacities by means of the slit-lamp long before they are visible on axial illumination with the ophthalmoscope, no matter whether a plane or a concave mirror is used. I have recently seen a case with massive choroiditis in one eye, but with the other eye normal as far as careful ophthalmoscopic examination could show. Examination with the slit lamp, however, showed delicate cobweb-like vitreous opacities in that eye too.

No doubt the slit-lamp will add enormously to what medical students of the future will have to learn about diseases of the eye.

DIAGNOSIS AND TREATMENT OF DIABETES MELLITUS IN HOSPITAL AND GENERAL PRACTICE.

BY EDWIN G. B. CALVERT, M.D. BELF.,
M.R.C.P. LOND., D.P.H.,
ASSISTANT, MEDICAL CLINICAL UNIT, ST. MARY'S HOSPITAL, W.

OUR knowledge of the diagnosis and treatment of diabetes mellitus has accumulated rapidly of late. Investigations have been reported in detail on practically every aspect of the subject; many schemes of diagnosis and treatment are well known and appreciated, and yet students and practitioners repeatedly confront one with the difficulty of applying the scientific principles to general practice. What is the minimum of investigation required for diagnosis? Can a patient be treated satisfactorily at home? What is the simplest and most practicable method of constructing or measuring diets? What are the indications for insulin? Can it be used at home to the same advantage and with the same safety as in hospital practice? How is its dose regulated? In fine, what are the essentials of procedure? These are the points on which the practitioner wants information, capable of ready application. The question of prognosis also arises: Is the patient likely to recover a measure of tolerance to carbohydrates as the result of treatment? Or, if insulin is employed, must it be continued indefinitely or may improvement eventually lead to its withdrawal?

My original intention was to publish in detail the results of my investigations on the effects of insulin in diabetes, but as these results are, in the main, confirmatory of work already published by others, it was thought better to treat the subject in a more general way by trying to answer such questions as the above. The experimental and clinical findings will be utilised to support the views put forward.

1. DIAGNOSIS.

In considering the points of value in diagnosis, it will simplify matters if, first of all, we contrast the carbohydrate metabolism of the normal individual with that of the diabetic.

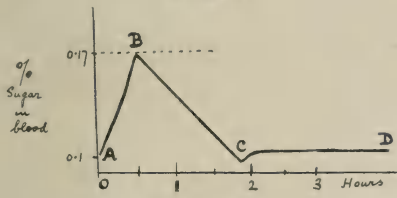
Investigation of Carbohydrate Metabolism.—Without entering into lengthy explanations of well-established facts, it may be stated at once that the nature of a person's carbohydrate metabolism can be determined sufficiently well by noting the variations that occur in the concentration of blood-sugar over a period of a couple of hours, following the ingestion, on a fasting stomach, of a moderate amount of carbohydrate. The latter is usually taken in the form of glucose (25–50 g.) and the blood-sugar estimated at half-hourly intervals for two hours; represented graphically this is known as a "blood-sugar curve." The term "fasting" is taken to mean before breakfast or four hours or more after a meal. It will be shown presently that more reliable results are obtained by carrying out such investigations before the patient has had breakfast. In a normal person from about two hours ($1\frac{1}{2}$–$2\frac{1}{2}$ hours) after a meal until food is taken again the percentage of sugar in the blood remains constant at approximately 0·1 (0·09–0·115); this concentration is known as the "fasting (or resting) level."

When carbohydrate is ingested, the blood-sugar rises in concentration as absorption proceeds, until the mechanism for its storage is so stimulated to action that the fasting level is regained within two hours. Below a certain maximum the amount of carbohydrate taken regulates the height to which the blood-sugar rises—e.g., 10 g. carbohydrate will cause a rise to about 0·13 per cent., 15 g. to, say, 0·14 or 0·15 per cent., whereas 30–50 g., or more, produce a concentration of approximately 0·17 per cent. (0·16–0·19)—a maximum or "threshold" which, in normal metabolism, cannot be forced; glycosuria does not occur.

There is still doubt as to the exact nature of the mechanism of storage, but for present purposes it may be regarded somewhat as follows. The store-houses of carbohydrate—the liver and muscles—are controlled, as far as glycogenesis and glycogenolysis are concerned, by the internal secretion of the pancreas, and the activity of the latter is, in turn, dependent on the concentration of sugar in the blood, a rise above the resting level acting as a stimulus. When only a small amount of carbohydrate is ingested, the blood-sugar has only risen a little when storage causes it to fall again. On the other hand, if larger amounts be taken, it would appear that the stimulus of a higher (or the "threshold") concentration is necessary before the mechanism is adequately set in action.

The apex of the blood-sugar curve generally occurs half to one hour after ingestion. (See Chart 1.) The glucose is given at A; at B storage comes into full play; at C the fasting level has been regained. The apex B is remarkably constant in height for the same individual, no matter how large the intake of carbohydrate (short of upsetting the stomach)—the threshold (at 0·17 per cent.) constituting an effective barrier to glycosuria.

CHART 1.

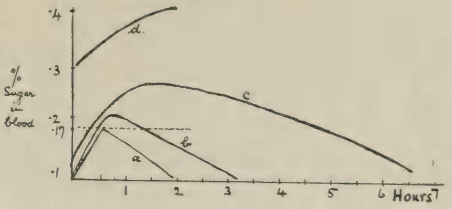


The outstanding characteristic, however, of normal sugar metabolism is the rapidity and the effectiveness of storage—the prompt return to fasting level within two hours. After the age of about 40 or 45 years two and a half hours may be required. From what has already been said, it will be understood that this phenomenon is dependent on: (1) the efficiency of the pancreatic hormone—insulin; (2) the efficiency of the liver and tissues to store carbohydrates. The endocrines generally and the related vegetative nervous system also play a part. In diabetes mellitus it is the pancreatic hormone that is at fault. Implication of the other factors is readily recognised by the associated signs and symptoms, and will not be considered here.

In Chart 1, then, the fall of the curve from B to C may be regarded as primarily due to a normal output of insulin by the β cells of the pancreas when stimulated by the rise in blood-sugar. The insulin may be said to throw open the carbohydrate depôts for purposes of storage. The fall of the curve to fasting-level indicates that storage is greater than assimilation, while the maintenance of this level—C to D—shows that the two processes are now running pari passu. I have found, in common with others, that as much as 20 per cent. of a large carbohydrate meal may be recovered from the stomach after the blood-sugar had fallen to normal; absorption was still proceeding, but at a gradually diminishing rate—the activity of the storage mechanism subsided in proportion. That the latter is true is demonstrated by giving a large meal of carbohydrates, and then noting the effect on the blood-sugar of a second meal given after a varying interval from the fall of the curve. As long as absorption and storage are still in progress, the shorter the interval the lower and more prolonged will be the second curve. On the other hand, if absorption be over and the storage mechanism rested a normal curve may be obtained. The force of this observation will be appreciated when we come to treatment.

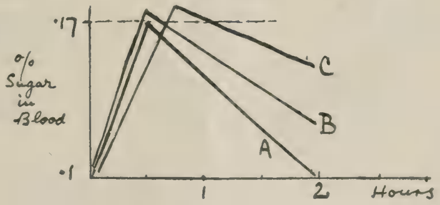
From the point of view of diagnosis, diabetes mellitus may be defined as a disease in which glycosuria occurs as a result of faulty storage of carbohydrates. In its incipient stages blood-sugar estimations show that the fall of the curve is slower than normal: at the two or two and a half hour period the fasting level has not been reached—e.g. the concentration may be 0·13 or 0·14 per cent. As the disease progresses this figure rises to 0·15, 0·16, or more, the blood-sugar requiring an increasing length of time to return to the normal. The longer the concentration remains above the resting level the greater will be the stimulation, and therefore fatiguing, of the islets of Langerhans and the less the time for their recuperation; a vicious circle has thus been set up. The curves are not only lengthened but gradually increased in height; the threshold is forced and glycosuria occurs. In such a case as this let us consider what happens in the course of a day. The hyperglycæmia resulting from breakfast may not have subsided when lunch time arrives; the exhausted islets are unfit to resume their work, storage becomes more and more ineffective, and it is easy to picture the advanced stage in which the blood-sugar is in excess next morning. In Chart 2 are shown blood-sugar curves after a dose of 30 g. glucose in (*a*) a normal person; (*b*) a patient with a slight defect of storage; (*c*) moderate diabetes; (*d*) marked diabetes.

CHART 2.



At this juncture it is opportune to raise the question of the best time to obtain blood-sugar curves. A short time ago Oliver and Haworth[1] pointed out the effect of fat on blood-sugar curves in the normal. They showed that excess of free fat in the blood interfered with absorption of glucose by the tissues. This is well illustrated by giving a fairly large amount of fat three to ten hours before the ingestion of the sugar. The following experiments by the writer will serve as examples:—

CHART 3.



A normal man, 30 years of age, given 50 g. glucose on a fasting stomach at 9 A.M. The blood-sugar curve is shown as A in Chart 3. On the following day the same amount of glucose was given mixed with 2 oz. of butter; the curve obtained is shown as B. A third experiment was performed next day: at 5.30 A.M., 2 oz. butter given, and a curve obtained for 50 g. glucose given at 9 A.M. (see curve C). The curve C in particular is suggestive of that of an incipient diabetes.

---

[1] THE LANCET, 1923, ii., 114.

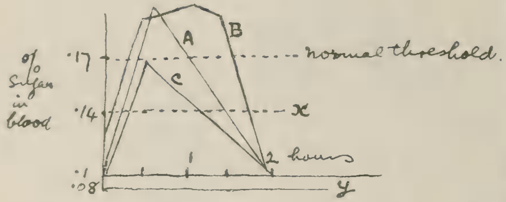
If the fat be taken 12 to 20 hours before the dose of sugar the curve is normal. Fat assimilated into the tissues promotes rather than inhibits storage. Accordingly it is better to obtain blood-sugar curves before breakfast, but when this is impossible, four hours or more should elapse after food before investigations are begun, and the patient should have been warned previously that fats in the meal are to be reduced to a minimum.

Types of Glycosuria.

Two other types of glycosuria must always be borne in mind: (*a*) renal glycosuria; (*b*) "lag" (or "delayed stimulus") glycosuria.

Renal Glycosuria.—In this somewhat rare condition the threshold for sugar is low, while the variations that occur in blood-sugar concentration are normal; there is no defect of storage. Instead of the threshold coinciding with the apex (0·17 per cent.) of the blood-sugar curve, it may, for example, be only at 0·14 per cent. (see *x*, Chart 4). Glycosuria is present while the blood-sugar is above the threshold and absent in the intervals. Sometimes the threshold is even lower than the normal fasting level (see *y*, Chart 4); in such cases the glycosuria is continuous, being, of course, increased when the blood-sugar is raised.

CHART 4.



"*Lag*" *Glycosuria.*—This anomaly is one in which the blood-sugar curve rises above the normal threshold, but, unlike the diabetic, returns to resting level within two hours. Glycosuria results while the threshold is exceeded and is necessarily intermittent. The condition still awaits adequate explanation. It would seem that a concentration of blood-sugar higher than usual is necessary to induce storage. It is worthy of note that out of the seven cases I have investigated during the past two years three were decidedly neurotic, two showed instability of the vegetative nervous system, and two appeared to be otherwise normal.

Two examples are given in Chart 4. A is from an otherwise normal patient; B from a highly neurotic man who had despaired of a cure after eight years of strict dieting. The health of the latter has improved greatly on a liberal diet, but the blood and urine findings remain unaltered. The condition is apparently not detrimental to carbohydrate metabolism, and no treatment is indicated beyond attention to the general health. Renal glycosuria is harmless and requires no treatment.

Essentials of Diagnosis.

In discussing the subject it is assumed that due attention has been paid to the history and to the general clinical condition of the patient, with a view to eliminating such causes of glucose in the urine as irritative lesions of the central nervous system, hyperactivity of the endocrines (thyroid, pituitary, or adrenals), sepsis, excitement, alcohol, and drugs. In pregnancy, if a reduction occur in the urine one must distinguish between glucose and lactose. Glucose, but not lactose, is fermented by yeast. Lactosuria is most often found in the last few weeks of pregnancy or after the child is born, but may be earlier. It is a harmless condition which disappears when lactation ceases. The fermentation test should always be applied if there be any doubt as to the nature of the reducing substance.

Glycosuria may be negligible or it may be of serious significance. It should, first of all, be ascertained whether sugar is constantly present in the urine or occurs only after meals. Sugar appears in the urine when the concentration in the blood rises above the threshold. This takes place: (*a*) In diabetes mellitus because of defective storage; (*b*) in renal glycosuria because of a low threshold, storage being normal; (*c*) in "lag" glycosuria apparently because a concentration of sugar higher than usual is necessary to set in action an otherwise normal storage mechanism.

Normal and Faulty Storage, as Indicated by Urine Examination.—Now let us consider whether it be possible to distinguish normal from faulty storage by urine examination alone. For reasons already given it is best to study the effects of the first meal of the day. Three specimens of urine are collected as follows:—

1. Bladder emptied, say, at 6 A.M., and urine discarded. Spec. A collected from 6–8 A.M.
2. A carbohydrate breakfast is then taken at 8 o'clock—either 3–4 oz. white bread (a cup of tea is allowed), or 1½–2 oz. cane sugar, or 30–50 g. glucose. Spec. B is collected by *thoroughly* emptying the bladder three hours later—i.e., at 11 A.M.
3. Spec. C is obtained an hour or so afterwards and before the next meal.

The three hours allowed for spec. B ensure that any sugar escaping through the kidney, during the two hours required for a blood-sugar curve, reaches the bladder. The results obtained in the three types of glycosuria mentioned are as follows:—

1. *Renal Glycosuria.*—(*a*) When the threshold is lower than the fasting level, say at 0·07–0·08 per cent., sugar is excreted continuously, but is considerably increased in amount when the blood-sugar is raised by taking carbohydrate. Since storage is normal, the fasting level is restored within two hours, and sugar excretion subsequent to this is the same as before the meal. Specimens A and C thus contain only very small, and approximately equal, amounts of sugar (0·5 per cent. and under), while that in spec. B is relatively large (see *y*, Chart 4). If the amount of carbohydrate ingested be increased—e.g., doubled—the results are similar.

(*b*) When the threshold is lower than normal, but not so low as the fasting level. Here sugar is absent from specimens A and C, but present in B (see *x*, Chart 4). Increase of the carbohydrate meal does not appreciably increase the sugar in spec. B.

2. "*Lag*" *Glycosuria.*—The same remarks as in para. (*b*) again apply.

3. *Diabetes Mellitus.*—In attempting to diagnose the glycosuria of diabetes mellitus from the above, it must be remembered (1) that storage is defective, (2) that sometimes, especially in cases of long standing, the renal threshold is so raised as to permit of a marked "diabetic curve" being obtained, and yet little or no sugar is found in the urine. Sugar may or may not be found in spec. A; if present, the percentage may be high or low, depending on the above factors. The foregoing remarks on renal glycosuria will make it clear that a high concentration is almost certainly due to diabetes; a medium concentration, say, 1–2 per cent., is at least very suggestive. As regards specimens B and C: It is only reasonable to expect that defective storage will reveal itself by the findings in one or other, or both, of these specimens, especially if a second set of observations be made, after double or treble the amount of carbohydrate has been given. For example, if appreciably more sugar be found in spec. C than in spec. A (which may contain none) the conclusion is that the normal fall of blood-sugar did not take place—the sugar concentration remaining sufficiently long above the threshold to cause an outpouring of sugar into spec. C. Increase of the dose of carbohydrate accentuates the difference between specimens C and A; it will also cause an increase in spec. B. These results indicate faulty storage. In the case where spec. A contains no sugar, and, after giving, say, 3–4 oz. bread, or 30–50 g. glucose, spec. C also contains none, either because the disease is slight or the threshold is raised, the distinction from a renal glycosuria, which gives similar results, is made by repeating the investigation on the following morning, using about twice as much carbohydrate. In renal glycosuria, all three specimens remain unaltered, while in diabetes the sugar content of spec. B is increased, and it is almost certain that sugar will now be found in C.

The tests may be briefly summarised as follows:—

Normal Storage (*Renal Glycosuria or Lag Glycosuria*) *is present* (*a*) if no sugar in both A and C with either the small or large amount of carbohydrate, especially if the larger dose cause no increase of the sugar in B; (*b*) if only small and practically equal amounts of sugar in A and C which are uninfluenced by increasing the carbohydrate taken. Spec. B also remains unchanged.

Deficient Storage.—(*a*) The more the concentration of sugar in spec. A exceeds 1 per cent. the more certain the diagnosis of diabetes mellitus; 1 per cent. itself is very suspicious. If the case be one of diabetes, fasting will lower the amount of sugar in A, whereas if renal glycosuria the condition remains much the same. In diabetes the amount of sugar in C is greater than in A, and varies directly with the quantity of carbohydrate ingested. (*b*) If no sugar in A but sugar in C, especially if increased with the large dose of carbohydrate. (*c*) If no sugar in A and none in C, even when the large dose of carbohydrate has been taken, but the amount in B has been appreciably increased. The absence of sugar in C in such cases is rare; the condition is generally one of mild chronic diabetes in which the renal threshold is high. If possible, the diagnosis should be confirmed by investigation of the blood-sugar. Provided care is taken that the bladder is thoroughly emptied when collecting spec. B, such tests, used in conjunction with the clinical evidence, are of great value in diagnosis. The presence of diacetic acid in the urine is most important: it goes far to confirm a diagnosis of diabetes mellitus.

I have checked these urine tests by simultaneous blood-sugar estimations, and find that, although they do not afford the same degree of information and are not as accurate as blood examinations, they are of real service to the practitioner who is unable to carry out the latter. Blood-sugar estimations, where at all feasible, are always to be recommended.

Blood Examination Required for Diagnosis.—The question now arises: What is the minimum of blood examination required for diagnosis? This is readily answered by reference to the remarks on normal and diabetic blood-sugar curves. The outstanding point of distinction between the two types is the failure of the diabetic curve to regain the normal fasting level within two hours (two and a half hours in elderly patients) after carbohydrate intake. Therefore, if a single blood-sugar estimation is made at the expiration of this period, one is able to judge how far the storage mechanism falls short of the normal; a raised fasting-level is equally significant. Such evidence of defective storage, together with the clinical signs of the disease, particularly if an appreciable amount of diacetic acid be found in the urine, leaves no room for doubt as to the nature of the condition. Of course, a more comprehensive idea of the state of carbohydrate metabolism may be obtained by finding the concentration of the blood-sugar before anything has been taken, and at intervals of 30 to 40 minutes for two hours after the meal. An intermediate procedure would be to make only three estimations: (*a*) One before the meal, (*b*) one 40 minutes after the meal, and (*c*) one at the two-hour period.

2. TREATMENT.

The treatment of diabetes mellitus, if it is to be effective, must be based on a sound appreciation of the patient's condition—the severity of the disease and the nature of the determining or contributing factors. A thorough search should be made for infections, attention being particularly directed to the gums, tonsils, nose, ears, lungs, heart, pericardium, urinary tract, and skin. Infections greatly aggravate the disease and should be eradicated as soon as possible. In case of necessity, local and spinal anæsthesia are usually permissible, but general anæsthetics are dangerous, the already crippled pancreas being often seriously damaged thereby, while coma may supervene. Since the introduction of insulin it has been found, however, that when the patient is given a preliminary course of treatment with this remedy, a fair margin of safety is obtained. Again, diabetics should take every precaution to guard themselves against infectious diseases, such as influenza, bronchitis, pneumonia, &c.; even the common cold is capable of greatly accelerating the disease, or, in the arrested case, of inducing a relapse.

The underlying principle of treatment should be to aim at recovery of the overworked or diseased islets of Langerhans. Arrest of the disease or recovery is only to be secured by their physiological rest. At the same time, it must not be forgotten that adequate nourishment is necessary; the general well-being of the patient counts for much.

To attain these results two lines of treatment are at our disposal: (1) Dietetic measures alone; (2) dietetic measures plus insulin. The problem is how to apply them with the greatest advantage to the patient and in the most practical manner.

It is well to realise at the outset that no two cases of diabetes are alike—each is a law unto itself and must be treated accordingly. That this variation does occur is readily understood when the number of factors involved is taken into account—the metabolism of carbohydrate, protein, and fat, singly or collectively, is affected to different degrees, the response of the organism as a whole to the disease varies, heredity probably plays a part, &c.

The following particularly influence one's attitude to the case: (*a*) Age of the patient; (*b*) state of nutrition and general condition; (*c*) severity of the disease, and whether it is in an acute or chronic stage; (*d*) if there has been previous treatment, its nature, duration, and results.

The advent of insulin has necessitated a revision of our methods of treatment and views on prognosis. The dietetic measures instituted by Allen, Graham, and others, however, still hold good and suffice in many instances. Other cases are almost unaffected by dieting and go steadily, often rapidly, downhill. It is in these that insulin displays most strikingly its beneficial effects. By careful correlation of the dose, and the amounts of carbohydrate, protein, and fat in the dietary, one is enabled not only to supply sufficient nourishment, but to rest the islet cells by maintaining a normal blood-sugar.

The question of treatment, then, largely resolves itself into whether insulin should be given or not. The circumstances of the patient will modify this to some extent—e.g., whether the patient is in hospital or at home; if the latter, the cost of insulin, and the possibility of attending to all the details that make for ideal therapy in hospital, are points of importance.

The treatment of diabetes should be viewed as treatment and investigation combined. The response to measures adopted affects our judgment of the severity of the disease, suggests the prognosis, and regulates further action.

I have found it convenient for purposes of, at least, initial treatment to classify diabetes as follows:—

Class A: (1) Acute, or rapidly advancing disease; (2) chronic disease which has seriously affected the patient's health; (3) diabetes of any degree in a young person; (4) threatening or actual diabetic coma.

Class B: (1) Mild chronic, or very slowly progressive disease in a patient of good nutrition, especially if the patient is elderly and obese, and has not had thorough dietetic treatment. Signs of arteriosclerosis are often present.

Class C: The intermediate type of case.

Class A is treated with insulin. Dietetic measures alone generally suffice for Class B; at least, there is no urgency for insulin. As regards Class C: If there be any doubt as to the state of the disease, or if it be of medium severity, it is wiser to employ insulin. It is even more important to control accurately the diet when insulin is being given than when it is not. Any difficulties that may exist in insulin treatment are associated more with the measurement and distribution of the diet than with the adjustment of the dose of insulin. The remedy cannot be used to the best advantage unless the patient be dieted scientifically.

Dietetic Treatment.

The Class B patient generally does quite well on dietetic measures alone. Suitable dieting will render the urine sugar-free and reduce the ketones, if present, to a negligible quantity, or abolish them entirely. The blood-sugar falls simultaneously and the morning fasting level may become normal, but it is doubtful if ever the normal blood-sugar curve is restored. In the majority the symptoms clear up rapidly if the diet furnish the minimum requirements for health without the reappearance of glycosuria or ketonuria. In these chronic cases the threshold is sometimes raised, and consequently, quite a marked "diabetic curve" may be obtained without the occurrence of glycosuria. Recently I encountered an interesting case of this sort:—

A chronic diabetic, aged 50, who had been kept free from glycosuria and ketonuria for years by dietetic measures, developed diabetic peripheral neuritis; there were absence of deep reflexes, hyperalgesia of the muscles, and considerable weakness of the legs—a partial foot-drop was present. A blood-sugar curve to 25 g. glucose showed a fasting level of 0·128 per cent., 0·250 per cent. at one hour, and 0·161 per cent. at two and a quarter hours, and yet no sugar was found in the urine over the period of the test. Rearrangement of the diet and a few doses of insulin so reduced the hyperglycæmia and improved the patient's condition that within a couple of weeks the hyperalgesia and weakness of the legs had practically gone and the reflexes were just making a reappearance.

Calorie Requirements for Health.

Calories required in 24 hours by adults: At rest, 11 calories per lb. body-weight; at light or moderate work, 14 calories.

Thirteen (or 12) calories per lb. is a convenient initial value for all adult cases; a patient weighing 140 lb. would thus require about 1820 calories. If the weight for height and age be abnormally high or low, then a correction should be made in order to approximate to the normal, by decreasing or increasing, respectively, the number of pounds before multiplying by 13.

In children metabolism is more active and consequently a greater number of calories must be given: At 2 years, 30 calories per lb. body-weight; at 5 years, 25 calories; at 10 years, 20 calories; at 15 years, 15 calories.

Calorie value of foodstuffs: 1 g. carbohydrate (C.) = 4 calories (approximately); 1 g. protein (P.) = 4 calories; 1 g. fat (F.) = 9 calories.

In health the diet is on an average composed of: C., 4/7; P., 1/7; F., 2/7; but in diabetes the diet is almost entirely made up of the latter two.

A certain minimum of protein must be given: About ½–¾ g. protein per lb. body-weight. In young people where growth is active this may be increased, with benefit, to 1 g. The requirements of carbohydrate and fat vary in every case and can only be ascertained by trial. In my experience, however, the majority of patients of this class eventually do best on a dietary containing about (an average): 0·3 (0·2–0·4) g. carbohydrate, 0·7 g. protein, 1·0 g. fat per lb. body-weight (= 13 calories per lb.) (due allowance being made for overweight or underweight). Thus a patient weighing 140 lb. would receive 42 (28–56) g. C., 98 g. P., 140 g. F. Cases with ketonuria, however, generally require less fat. In others, especially if the patient is obese, a reduction of the fat content of the diet often leads to more rapid progress. The various steps in treatment will be described presently.

The experiences with insulin and the details of dietetic treatment follow.

(To be continued.)

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

A meeting of this section was held on June 13th, Mr. A. L. Whitehead, President of the section, being in the chair.

Dr. George Riddoch and Mr. Charles Goulden collaborated in a paper on the

Relationship between Sub-arachnoid and Intra-ocular Hæmorrhage.

Dr. Riddoch said the not infrequent occurrence of hæmorrhage into the sub-arachnoid space within the skull had long been known, but mainly as a cause of death in cases in which an incorrect diagnosis had been made during life. No distinctive symptomatology had been associated with it, hence it was regarded as unrecognisable at the bedside, and its outcome was regarded as fatal. But it had been found that the presence of blood on lumbar puncture indicated bleeding into the sub-arachnoid space. Ætiologically, there were three main groups of cases: (1) Those with traumatic rupture of meningeal vessels; (2) cases of bleeding into the sub-arachnoid space secondary to intracranial hæmorrhage; (3) cases of primary non-traumatic rupture of a meningeal vessel or aneurysm. The third group was the most interesting, and knowledge on this had been much added to by C. P. Symonds, so that it could now be diagnosed with reasonable certainty without the aid of lumbar puncture. Cases often occurred at an age when intra-cerebral hæmorrhage was not very common. In the present authors' series the ages were 43, 44, 46, and 53. Several authorities attributed the lesion to rupture of a congenital aneurysm of one of the basal arteries. Arterial hypertension was often absent from these cases. A frequent feature of such hæmorrhage was bleeding into one or both eyes. One of the four patients here reported died, and an eye was removed and examined histologically with the object of ascertaining by what means the intra-ocular hæmorrhage occurred. The contribution dealt with this case specially. The man was aged 44, and he was admitted to the London Hospital last February, under Mr. Russell Howard. His previous health had been good, except that he probably had sunstroke while in Palestine. While going upstairs he suddenly fell down, but did not lose consciousness and walked up to his room. A little later he was heard to fall and was found unconscious. He had three successive fits at short intervals, foaming at the mouth; he was convulsed and cyanosed. In the second fit, opisthotonos occurred. He was admitted to the London Hospital in a state of "cerebral irritation"; he resented examination or questioning. His pupils were of medium size, equal, and reacted to light and to accommodation; he had full ocular movements. All tendon-jerks were exaggerated, and the plantar response was extensor on both sides. Sensation seemed good. Blood-pressure readings were 140–180; temperature 97° F.; pulse 100, full and strong; respirations 24. Three days later his muscles were flaccid, his tendon-jerks were difficult to evoke, but the plantar reflexes were normal. Three days later still he had diplopia on looking to the right, and his tendon reflexes were absent. In a day or two the diplopia disappeared, but otherwise there was no change. A few days later he had difficulty in swallowing, and was very drowsy, the left side of his face was weak, and his tongue was protruded to the left. No tendon-jerks could be obtained, and, for the first time, there was incontinence of urine. The blood pressure was 140-190. Twelve days after admission he was stuporose and cyanosed, the breathing stertorous, at 34 per minute, pulse 114, temperature 102° F. Both fundi showed hæmorrhages in the neighbourhood of the discs, and the latter were swollen. The left fundus showed two large crescentic hæmorrhages along the inferior veins near the disc margin. The pupils were equal, and reacted well to light; there was a flaccid left hemiplegia. The heart's apex beat could not be felt, and his noisy breathing prevented the heart sounds being heard. The base of each lung was congested. The lumbar fluid was pink, and contained blood and a slight excess of lymphocytes. Wassermann was negative. He died on the thirteenth day of his illness, with a temperature of 104·2°, pulse 132, and respirations 62. Red-brown blood and a small blood-clot, together a few drachms, were found in the subdural space, and in the posterior part of the longitudinal fissure were two symmetrical areas of sub-arachnoid hæmorrhage; other collections of blood were scattered over the cerebral convexities, and much red and brown blood-clot lay under the arachnoid in the right Sylvian fissure, and a smaller amount in the left Sylvian fissure, anterior part of the median fissure, and cisterna basalis. A saccular aneurysm, a centimetre in diameter, projected backwards from the right intracranial carotid at the origin of the right middle cerebral, and it had been ruptured at its inner pole. Within the orbits the sheaths of the optic nerves were distended with blood. When the right eyeball was opened, multiple hæmorrhages were seen round the margin of the optic discs, the two largest lying on vessels. Purulent bronchitis and broncho-pneumonia were in the lungs. There was only moderate atheroma, but the left kidney was grossly atrophied and fibrotic, and its pelvis was cystic and projected inwards. There was no abnormality of renal vessels.

Discussing the clinical picture of rupture of a basal aneurysm, Dr. Riddoch said the patient in many cases had been said to have good health until the attack, but careful inquiry showed there had been headache, giddiness, defective memory for recent events, &c.; also there was usually tinnitus with periodic exacerbations. One of the four patients now dealt with had had periodic attacks of epistaxis, the bleeding having been preceded by lethargy and yawning with a sensation of heat on the vertex. On the epistaxis commencing he felt very much better and the symptoms disappeared. The onset of the seizure was always sudden. Usually the bursting of the aneurysm synchronised with some form of activity, which for the time raised the blood pressure. The coma into which the patient passed might rapidly become profound, all the signs of cerebral and medullary compression appeared, and he might die within a short time. More characteristic, however, was the clinical picture which, apart from the onset, resembled that of meningitis. Signs of local disturbance of neural function were always present, but usually slight. Frequently there were bilateral signs of pyramidal disturbance, such as diminished abdominal reflexes, increased tendon-jerks, and an extensor plantar response. An almost constant sign was rigidity of the neck, and Kernig's sign was often positive on both sides. An invariable sign of great importance was the presence of blood in the spinal fluid. With regard to the course of the complaint, recovery from at least the first seizure was common; after two or three weeks there was a return of consciousness, any palsies disappeared, and the reflexes became normal. Sometimes, however, the slight mental defects, such as unreliable memory, remained. But when vitreous or sub-hyaloid hæmorrhage had occurred, vision seemed to be more or less permanently impaired. One of the cases now narrated had had at least four seizures in 3½ years, and was still alive.

Mr. Goulden dealt with the ophthalmological aspect of the question in great detail, pointing out, first, the intimate anatomy of the parts concerned. With regard to the ophthalmoscopic signs, care must be taken not to confound these with those due to injury of the optic nerve following fracture of the base of the skull in the neighbourhood of the optic foramen and effusion of blood into the nerve sheath. The cases now being discussed were those in which there was no direct injury to the optic nerve by any such object as a spicule of broken bone, or any damage to the nerve by a sudden strain or crush such as occurred when there was a fracture in the orbit or optic foramen. The most common abnormality in the case was papillœdema, and it was usually bilateral and of remarkably rapid onset. The veins were always engorged and tortuous. Ophthalmic symptoms were not mentioned in any of these four cases, and as the patient was overcome by unconsciousness, that was not remarkable. The sheath of the nerve was tensely filled with blood-clot, which gave to the sheath the appearance of a distended vein. There was no infiltration of the nerve itself with blood; the blood-clot was delimited by the pial sheath. The sub-arachnoid space was full of blood. His conclusion was that the trouble consisted in interference with the venous return from the retina and optic nerve.

Mr. Leslie Paton pointed out that papillœdema did not quickly appear in all the reported cases of the condition. There was a type of papillœdema not necessarily associated with direct pressure from hæmorrhage in the nerve sheath, and in some cases in which the hæmorrhage was insufficiently severe to cause a rise in intracranial pressure the patient was dead before papillœdema could occur. In some cases there was a huge subhyaloid hæmorrhage without any distension of veins at all, and when, later, the disc could be examined, there was no sign of papillœdema, yet there were signs of hæmorrhage round the edge of the disc and of the physiological pit.

A Case for Diagnosis.

Mr. F. A. Williamson-Noble showed a case for diagnosis. When he first saw the patient the fundus appearances suggested retinitis punctata albescens; the appearances in the two eyes were similar. There was a bright spot at the macula. The peripheral part of the fundus in both eyes was slightly albinotic, and some of the retinal pigment could be made out here. The colour of the spots was about the same as that of the peripheral fundus; there were no such spots in the periphery. The fields were full, there was no night blindness, and the vision of each eye, with correction and a dilated pupil, was 6/9 full. It seemed unlikely, therefore, that the condition could be retinitis punctata albescens. Another possibility was that the condition might be due to multiple colloid excrescences of the membrane of Bruch. In a case of that kind, which the late George Coats published, the affected areas had a flat, scaly appearance, which showed a distinct glitter on movement of the light, and seemed to be a little raised above the level of the fundus. That patient, when seen, had been suffering from bilateral glaucoma for nine months, and the vision in the right eye was reduced to fingers at three feet, and in the left to mere perception of light. In the present case the dots did not glitter and did not appear to be raised above the general level of the fundus. This patient had no symptoms; the Wassermann test was negative and urine normal. He did not think such an extensive change could be inflammatory or there would be loss of vision. His suggestion was that the yellowish-white dots represented small localised bosses of the retinal pigment epithelium.

Dr. Rayner Batten projected on to the screen illustrations of two cases having a somewhat similar appearance. Here, again, there was no defect of vision, and there had been no material change during a long period of observation—in one case over 20 years. There was no evidence of disease in either patient.

Mr. Malcolm Hepburn said he considered these were usually cases of hyaline degeneration of the membrane of Bruch. Generally the areas of degeneration were surrounded by small areas of pigment. In the case now shown there was little pigment, but that did not necessarily militate against the view he had expressed, and it was supported by the fact that there was no interference with vision.

The President commented on the fact that in one of Dr. Rayner Batten's cases the dots were associated with opaque nerve-fibres; he thought that this was in favour of their being a congenital condition.

A Modification of Elliot's Scotometer.

Mr. Frank Juler showed a modification of the ordinary Elliot scotometer, for which instrument he expressed much admiration. Its fault was that it needed a second person to help in recording the readings taken. He got the instrument-maker to fix a rim round the edge of the rotary screen, so fixed and marked by angular degrees that it was visible from the front. This rendered it a one-man instrument.—Mr. R. Pickard described a method by which he had achieved the same object. He used a canvas screen, painted in dead black, and tangent circles also painted in black, but raised slightly above the surface so that they could be seen. He could use the instrument without assistance, and take fields quickly.

MEDICO-LEGAL SOCIETY.

OSTEOPATHY IN ITS MEDICO-LEGAL ASPECTS.

A MEETING of this Society was held at 11, Chandos-street, London, W., on June 17th, Sir **WILLIAM COLLINS**, in the absence of the President, being in the chair. After the business of the annual general meeting had been completed, Dr. **NORMAN J. MACDONALD** read a paper on Osteopathy in its Medico-legal Aspects. He said that in the United States of America there were two types of doctors—those holding degrees of M.D., who practised medicine on the lines recognised in this country, and those holding the degree of D.O. (doctor of osteopathy), who were legally entitled to practise with no other limitation than that they should not prescribe drugs. Even this limitation upon osteopathic practice had been removed in at least one State by a recent decision in the courts. The object of his paper was to demonstrate the value of osteopathy and to point out some of the legal aspects of osteopathic practice which might arise in this country. Osteopathy could be defined as a method of dealing with disease by spinal manipulation, and was founded on the belief that many diseases were the result of minor displacements of the vertebræ. The causes of these displacements (or lesions) were either violence or failure on the part of the body to react to environment. As an example of the first type he instanced the pain in the right shoulder and arm produced by over-reaching while playing tennis. The osteopath, in such cases, generally found abnormal fixation of the first rib at the costo-vertebral articulation, and the condition was easily cured by suitable manipulation or massage. As an example of the second type, he took the attacks of "gastric inefficiency" which followed dining "not wisely but too well." A medical student who had consulted him for this condition exhibited rigidity of the upper dorsal spinal muscles, which could have been easily felt by any person; no special tactile sense was required to perceive the difference in tone between the muscles of the two sides. Here, again, suitable manipulations to free the vertebræ resulted in breaking a vicious circle and curing the condition. As a testimony to the success of the treatment the medical student stated that he was able subsequently to consume double the number of whiskies and sodas without ill-effects. The condition commonly found was one of semi-subluxation of the vertebræ; the vertebræ became fixed in some axis of movement, perhaps one not commonly used, and the fixation was sustained by rigidity of the muscles and thickening of the ligaments. The resulting train of symptoms was reflexly produced and tended to keep up the rigidity, thus producing a vicious circle. He believed that the sympathetic nervous system played a large part in the production of symptoms. From the point of view of scientific accuracy it was unfortunate that post-mortem demonstration of the lesions was generally impossible, as the muscles which played so large a part in the mechanism of the "lesions" were either relaxed or in a state of rigor mortis. Moreover, post-mortem examinations were only very rarely obtained at the osteopathic hospital at which the speaker had studied in America, since the patients were all private ones and the death-rate was in any case very strikingly low. Clinically, certain definite relationships between the site of the lesion and the symptoms were seen. Thus a cervical lesion was associated with cranial symptoms, and a lumbar lesion with lumbago or pain in the lower limbs. The manipulations practised by osteopaths were of the type employed by bone-setters and were painless, unless a joint affected by rheumatoid arthritis were involved. The speaker was gaining faith that the manipulations had a beneficial effect upon the blood circulation quite apart from any local effect that was aimed at.

Possible Legal Aspects of Osteopathy.

Accidents to workmen were commonly followed by shock and pains of an indefinite character. Cross-examined by counsel during the lawsuit that ensued, the doctor in the case would admit that there was no organic lesion resulting from the accident and would perhaps characterise the case as one of "traumatic neurasthenia." The osteopath believes that such cases are associated with a definite spinal lesion and that they are capable, if not always of cure, at least of very considerable amelioration by osteopathic treatment. The result of such cure or amelioration would be of enormous financial importance to insurance companies, which now have to pay large sums as compensation for incapacity following minor accidents. As examples of the type of case to which he referred, Dr. Macdonald quoted several cases. The first was that of a girl, aged 20, suffering from concussion following a blow on the head, who was admitted to the wards of St. Bartholomew's Hospital, of which he was at that time house surgeon. She made a partial recovery at the time but continued to attend the hospital under various physicians and surgeons complaining of headaches, from which no treatment appeared to give any relief. After an interval of two years, during which he had been studying osteopathy in America, she again consulted the speaker. He found the muscles of the neck tense and a definite lesion between the first and second dorsal vertebræ, for which he gave osteopathic treatment approximately three times a week for six or seven weeks. As a result she became quite free from headaches. After three months a return of the headache necessitated one further treatment which had apparently completed the cure. Another case quoted was that of a young man, the son of a provincial surgeon, who had a heavy fall and hurt his left leg. For three years afterwards he suffered from sciatic pain. An X ray showed only a chip off the great trochanter. Treatment of all kinds, including massage and stretching the sciatic nerve, had failed to give any relief. Finally, he was sent to the speaker, who found much rigidity of both sacro-iliac joints and a slight rotation of the spines of the lower dorsal vertebræ. Twenty sittings of osteopathic treatment had so relieved the patient that he was able to play games, and he had since only required three isolated treatments. Had this been a legal case it might have produced much trouble. After describing two or three more cases Dr. Macdonald proceeded to discuss the regulation of the practice of osteopathy. He pointed out that osteopathy had been established in the United States of America for over 50 years, and that it was spreading over the whole world. There were no less than eight schools of osteopathy in America, some of which had as many as 500 students. All these students without exception qualified and practised with State licences. The Medical Act of 1886 in no way prohibited unqualified practice in this country, and he thought it probable that osteopathy would in time grow to be almost as important and well established as it now was in the United States. He therefore pleaded that it was time that the whole subject should be taken up and investigated by the medical profession. With this end in view he had intentionally read a paper which approached the subject from an unexpected angle, and he expected and would welcome criticism.

Discussion.

Dr. **W. ATKINSON** said that Dr. Macdonald's paper amounted to a eulogy of osteopathy rather than a discussion of its medico-legal aspects. Indeed, it was difficult to see how there could be any medico-legal aspects to osteopathy until such time as a school of osteopathy was established and recognised in this country. Dr. Macdonald had not described the form of the osteopathic manipulations from which so much success was claimed. As a medical referee sitting with a county court judge he had had considerable experience of compensation cases and of sifting medical evidence. If the case for osteopathy were on trial he would find it difficult to advise the judge favourably to the lecturer's case on the evidence he had put before them.

Dr. M. I. Finucane inquired whether osteopathy was founded upon the principles of anatomy and physiology as they had become known to medical men by the patient work of 100 years. The "treatment" of which the lecturer spoke appeared to be a form of massage which, as was well known, was beneficial to muscular rigidity. To the treatment of such cases as the lecturer had described by osteopathic measures there could be no objection, but grave errors sometimes arose in the practice of the "unqualified" osteopath. The speaker had recently rescued three cases of organic nervous disease, one of disseminated sclerosis, one of paralysis agitans, and one of locomotor ataxy, from treatment by osteopaths. He agreed that the whole subject of osteopathy required ventilating, and suggested that two or three osteopaths should meet in conference a similar number of medical men and lay out their case in full.

Dr. F. O'Kinealy said that the Society was indebted to the courage of the lecturer, who must have been aware that his paper would be bitterly criticised. At the same time, he maintained that the cases quoted could have been equally successfully treated by ordinary medical methods. Rigidity of muscles was a reaction to injury. By causing hyperæmia of the part the osteopath was in some cases assisting Nature in the cure, but there was nothing new or sensational in the means he employed.

Dr. S. H. Belfrage discussed the attitude that the medical attendant should adopt when it was proposed to call in an osteopath. Personally, when the case was an acute or serious one, he opposed the suggestion as strongly as he could, but in cases which were not likely to suffer any harm from manipulations he allowed the patients to please themselves. He recently had a case of a tumour of the thyroid which had been treated for six months by a doctor of osteopathy, whose fees had amounted to more than £150. The case had now been cured by a surgeon. The answer to the question, "What is osteopathy?" was, he thought, "osteopathy is a creed." Those who believed in it and practised it had things made easy for them; no work was required, no thought need be expended over individual cases. The fact that "cures" had resulted proved nothing. If the osteopath was a man of personality he could do some at least of his patients much good.

Dr. A. S. Morley referred to a type of case which Dr. Sicard, of the Hôpital St. Louis at Paris, had been working on for some time in which there was an inflammatory condition of the connective tissue within the spinal canal. A case of this type, whom he had seen in consultation with an eminent physician and who, he had to admit, had derived no benefit from ordinary medical treatment, had been subsequently cured by an osteopath. Cases of this type, he was therefore convinced, did well with osteopathy.

Mr. H. B. Wells, speaking as a member of the Bar, thought medical men were very biased in their treatment of the "unqualified practitioner." Surely the fact that the lecturer had taken up osteopathy after qualifying in the proper manner in this country was sufficient to prove that there was something in osteopathy. He had often heard doctors admit that they could do nothing with "traumatic neurasthenia," and that the best thing insurance companies could do was to "pay up." It appeared to him that it was time osteopaths had a fair and unhampered trial in such cases at least.

Mr. A. M. M. Forbes, also a member of the legal profession, admired the courage of the lecturer, who had to face the bigotry of the medical profession in their outlook upon all other forms of practice, as was exampled by their attitude towards Sir Herbert Barker. He hoped that if osteopathy was any good the country might have the benefit of it.

Sir William Collins, speaking from the chair, said that the discussion had at least proved the catholicity of the Society's platform. He referred to the fact that the lecturer had taken the degree of D.O. after obtaining the conjoint qualification in this country. New light on medical science had often come from non-medical sources. Neither Pasteur nor Chadwick, the father of sanitary science, had any medical qualification. Medicine was not bigoted, but would accept good work from any source provided only that it would bear the light of searching scrutiny. Having had some experience of teaching and examining medical students in the past (in anatomy), he could not feel reassured by the statement of Dr. Macdonald that all the students of osteopathy obtained the diploma. He gave an instance of the ignorance of anatomy of a lady osteopath who did not know how many cervical vertebræ there were. It was an error to suppose that the law in this country prohibited "unqualified practice," for there was no bar except that imposed by the Venereal Diseases Act of 1917, which rendered the treatment of V.D. by unqualified persons illegal. Even the Insurance Act had provision for those who desired to be attended by a herbalist. He would ask the lecturer whether the X rays in the case of the surgeon's son showed any displacement of vertebræ corresponding with that which he had detected in the course of his examination.

Reply.

Dr. Macdonald said that "treatment" meant moving the spine until free movement was obtained in the direction required. Operations of precisely similar kind were practised by orthopædic surgeons at the Royal National Orthopædic Hospital in Great Portland-street. Skill was required to obtain the right movement of the correct vertebræ, while keeping the remaining vertebræ at rest. He agreed that osteopathy was a "creed"; it was founded by a medical man, Dr. George Still, who was dissatisfied with the treatment of disease by drugs. Unfortunately the teaching of osteopathy had now become a business, and the colleges where it was taught depended for their funds on the number of degrees which they conferred, so that inevitably a number of unsuitable people obtained the diploma. As regards the suggestion that three osteopaths should confer with three medical men, it was a curious coincidence that there were just three osteopaths in this country who held medical qualifications, the other two being relatives of his own, he thought that all would be glad to meet the suggestion. The cases he had quoted had all failed to derive benefit from orthodox medical treatment. In reply to the question of the X rays, he said he thought he could detect minor displacements in the X ray plates. A recent article in the *Journal of Radiology* discussed just such minor displacements of vertebræ as osteopaths based their work upon.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A meeting of this Association was held at the Elizabeth Garrett Anderson Hospital on June 17th. In the absence of the President the chair was taken by Dr. Amy Sheppard.

Dr. Christine Murrell read a paper on

Emergencies in General Practice.

She said that in most cases the difficulties and embarrassments of emergencies in general practice were due to the fact that on these occasions the doctor is the central figure, that everyone is standing around waiting for the doctor to do something, and that the atmosphere is one of hurry and agitation. If one remembered that in practically only two conditions—namely, foreign bodies in the air-passages and hæmorrhage—was excessive haste the one essential of success in treatment, it became clear that the usual emergency was really a matter for calmness and deliberation. Most emergencies happened at night—no doubt the physiologists could offer an ingenious explanation—and one was usually summoned to them by a messenger. It must never be forgotten that the messenger might be able to furnish most valuable information—e.g., in cases of poisoning—and much time may be saved in the long run by questions at this stage. Dr. Murrell then dealt seriatim with various kinds of emergency, telling many anecdotes illustrative of the dangers which might beset the general practitioner. Hæmorrhage and foreign bodies in the air-passages were dealt with as the most urgent conditions. Œdema of the glottis was another almost as urgent. Fractures were considered to be emergencies, allowing of deliberation and indeed demanding it, the imperative need for care here, especially the taking of an X ray plate for the protection of the practitioner, being stressed. Infectious diseases might prove of considerable trouble, especially when the diagnosis was not quite certain, and the question of the advisability of waiting for the result of the examination of a throat swab before giving antitoxin was discussed. No discussion of emergencies would be complete without mention of insanity, and the need for care in dealing with the certification of lunatics was dwelt on.

A discussion followed upon the treatment of lunatics and the difficulty of dealing with suspected diphtheria during the delay often involved in getting a swab examined. The following members took part: Dr. SHEPPARD, Dr. E. ROBERTS, Dr. AGNES KEEN, Lady BARRETT, Dr. ETHEL BENTHAM, Dr. MINA DOBBIE, Dr. ELEANOR LOWRY, Dr. JOSEPHINE FAIRFIELD, Dr. ADELAIDE RENSHAW, and Dr. MARY A. BLAIR.

Reviews and Notices of Books.

DIABETES MELLITUS.

The Antidiabetic Functions of the Pancreas and the Successful Isolation of the Antidiabetic Hormone—Insulin. By J. J. R. MACLEOD, Professor of Physiology, University of Toronto; and F. G. BANTING, Research Professor, University of Toronto. The Beaumont Foundation Lectures. Published under the auspices of the Wayne County Medical Society, Detroit, Michigan. London: Henry Kimpton. 1923. Pp. 69. 7*s.* 6*d.*

Two of these lectures were given by Prof. Macleod and one by Prof. Banting in January, 1923, and no more recent work is included in the book. There is an account of the early work on the pancreas, and this is the best which has hitherto been published, but there are no references to the papers. There is a good account of the structure of the islands of Langerhans and of the staining reactions of the granules which has enabled the differentiation to be made between the cells of the acinous portion of the gland and also between the α and β cells. The arrangements of the islands with regard to the small ducts and their abundant blood-supply are fully detailed. An account of the comparative anatomy is given, and the arrangement in the teleostean fishes in which the island tissue is separated from the acinous portion of the gland is described. The structural changes which occur after the ligation of the pancreatic duct have been carefully studied and are very complicated. The acinous cells degenerate quickly as well as some of the islands, but this is followed by a regeneration of the acinous cells and some of the islands. But the regenerated acinous cells again degenerate and this process is repeated several times; after four and a half months the pancreas consists almost entirely of island cells which have been regenerated, but there are still a very few acinous cells existing. It is of great importance to have these observations stated so clearly in a compact form as the separate existence of the islands has recently been called in question by H. Oertel and Swale Vincent in our columns. A comparison of their papers with the description given by Macleod is most instructive. The early experiments by Dr. Banting with Dr. C. H. Best, which led to the discovery and isolation of insulin and the early attempts at its standardisation and assay, are set out. The book is well printed but has no index.

Food Tables Compiled Particularly for Use in Treatment of Diabetes Mellitus. Second edition. By G. A. HARRISON, M.B. Camb., Biochemist, Hospital for Sick Children, Great Ormond-street; and R. D. LAWRENCE, M.D. Aberd. London: H. B. Skinner and Co. 1924. Pp. 28. 2*s.*

THE knowledge of the sugar content of the foods which a diabetic may eat is of great assistance to the patient. The monotony of his diet is distressing, and any table which sets out the facts clearly is a boon both to him and to his doctor, who is often faced with unexpected questions, and will be able to look up the facts compiled in these tables. The carbohydrate foods are set out very clearly, so that it is easy for the patient to substitute one kind of food for any other. The weight of different foods which contain 5 g. of sugar, together with the details of the way in which the food is prepared, are very convenient. The amounts of protein and fat are also given; the calorie value is omitted although it can be easily calculated. The second table gives the amounts of protein in the different foods which do not contain any sugar. The knowledge of the amounts of sugar in the different alcoholic beverages will be useful for patients with mild diabetes. The instructions for using the tables are clear, but their comprehension demands some knowledge of very elementary mathematics.

MORPHOLOGY AND EVOLUTION OF THE APES AND MAN.

By CHARLES F. SONNTAG, M.D., Ch.B., F.Z.S., Prosector to the Zoological Society of London and Demonstrator of Anatomy, University College. London: John Bale, Sons and Danielsson, Ltd. 1924. Pp. 364. 12*s.* 6*d.*

As Prof. Elliot Smith says in his foreword to this book, its importance depends upon the fact that it is an impartial and reliable statement of facts based upon direct observation, while it is a laborious sifting of the mass of writings dealing with the Primates. It is also more than these, for the information is conveyed in a way that makes the book pleasant to read, and any facts looked for can be found easily without wading through pages of irrelevant matter; moreover, the facts are presented impartially, opposing views are fairly stated, and a long and seemingly fairly complete bibliographical list is appended. We have read the work with interest and pleasure.

Dr. Sonntag here deals with the whole Order of Primates, a short but useful account of the lemurs, tarsius, and monkeys following a brief introduction, but the main part of the volume is given to the anthropoids. As in all works bearing on this subject, one gains the impression of marked plasticity of structure in the members of any of the groups included under the heading, in addition to the differences between the groups themselves. It is, of course, true that the human subject, especially the female, exhibits variations in structure, but apparently not by any means to the same extent as his so-called cousins. The muscular apparatus in the apes has always been a subject of great interest to investigators, and Dr. Sonntag gives a considerable amount of space to this matter. We note, among many facts of great interest to the human anatomist, that the gorilla seems to approach the human type nearer than the other anthropoids in the adult condition of the "contrahentes" of the hand, while the chimpanzee and gibbon appear in their adult states to resemble the human fœtus. A short but clear and good account of the adductors of the thigh will help to clarify the somewhat confused ideas obtaining on this subject.

Dr. Sonntag commits himself to the statement that the peroneus tertius is a "human muscle," and is absent in anthropoids; as a matter of fact, the muscle, as it is found in the human leg, has been described in these animals, and its appearance is another example of their plasticity. The occurrence of such a muscle in the chimpanzee has recently been described by Paul Hecker, and D. J. Merton in America has, within the last few months, described it in two gorillas. The accounts of the skeletal and muscular portions of the anthropoid economy are followed by those bearing on the digestive and absorptive system, circulation, ductless glands, and blood. A useful little summary of the precipitin reactions and syphilitic virulences are given here. In the description of the urogenital organs there is an account, apparently new, of the bladder of the chimpanzee, and some data about menstruation are given. The statement that copulation is *in modo quadrupedale* is not, we think, always true. The respiratory system, and a very useful chapter on the nervous system, complete the descriptive portion of the book. A summary of the main grounds for present-day views on the evolution of the Primates brings the work to an end.

The book is likely to be a work of reference on its subject for many years to come, and we recommend all who are interested in this matter to procure it.

QUAIN'S ELEMENTS OF ANATOMY.

Vol. IV., Part II.: Myology. By T. H. BRYCE. London: Longmans, Green and Co. 1923. Pp. 310. 25*s*.

THIS, the last addition to the eleventh edition of the leading English work of reference on anatomy, is a production on which all concerned, writers and publishers, are to be congratulated. We have gone through the book with pleasure and profit, finding not only a charm in the many beautiful illustrations, but coming across collected groups of data of information gathered from widely diverse sources and brought together in ways both interesting and instructive. Prof. Bryce has called in Prof. T. Walmsley's mathematical mind to deal with the action of most of the muscles in the body, and those who delight in angles and formulæ can enjoy themselves in the opening chapters of the book, while those who prefer the less exacting charms of morphological discussion will find this in profusion, interspersed with the many details of facts of descriptive anatomy. The nerve supplies of the muscles are dealt with *in extenso*, providing information which will be found of great value in all cases, and in some, we think, will be new to many readers. Most of the new illustrations, in colour, are from Mr. A. K. Maxwell's pencil, and are a prominent feature in the book. The work is one which, not taking account of its claim as a part of "Quain," is a necessity in any anatomical library.

HISTORY OF MEDICINE.

Lectures on the History of Physiology during the Sixteenth, Seventeenth, and Eighteenth Centuries. By Sir MICHAEL FOSTER. Cambridge: The University Press. 1924. Pp. 306. 15*s*.

THESE lectures were originally delivered as the Lane lectures at the Cooper Medical College in San Francisco during the autumn of 1900; they were first printed in 1901 and are now reprinted. There are some gifted writers who have the faculty of making even dry scientific subjects read like a veritable romance, and not only to the trained reader but also to any intelligent layman. Among such were Lucretius in early times, and in our own Sir Robert Ball writing on astronomy, Huxley on biology, and Foster on physiology. That sound and cultivated physician, the late Dr. James Andrew, had one reply to students who asked him the question: "What is the best book on medicine?" and it was "Foster's Physiology." The lectures now before us must have been a veritable revelation to those who heard them for the first time, for they bring before the reader a most vivid picture of the growth of our knowledge of the complicated processes of the energies of the living body.

Sir Michael Foster begins his course with Vesalius, his forerunners and followers, passing on to Harvey and the circulation, to Borelli and others on the new physics and the nature of muscular contraction, to Malpighi; and later to that curious and far-sighted thinker, Van Helmont, to whom we owe the word "gas," by which term he meant what we now call carbon dioxide, though he was ignorant of its nature. He had arrived at a very close approximation to the truth of the physiological processes of digestion and, ignoring the current teaching of his day that there are three digestions, he argues that there are six steps or digestions by which the dead food becomes the living active flesh. The active principle of all these is a ferment, and one ferment will not act in the presence of another. The first digestion takes place in the stomach, the second in the duodenum, the third in the mesenteric veins and the liver, the fourth and fifth in the heart and arteries, and the sixth "in the kitchens of the several members"; as Sir Michael Foster points out, Van Helmont had reached the conclusion that "all tissues live upon the common blood; and the power of assimilation lies in the tissue itself," or in Van Helmont's own words, "Each tissue maintains its own individual kitchen within itself." It is interesting to compare Van Helmont's doctrines with those current in the time of Macrobius 380 A.D., who, in Book VII., 4, 23, of his Saturnalia, makes Disarius, a physician, point out that the food undergoes four digestions—in the stomach, in the liver, in the veins and arteries, and in that process by which every member of the body takes up that which is necessary for it, "Haec est quarta digestio, quae in singulis membris fit, dum, quod unicuique membro datum est, ipsi membro fit nutrimentum"; a doctrine practically the same as that of Van Helmont, who may have been acquainted with Macrobius.

Other of the lectures deal with Sylvius and the physiology of digestion in the seventeenth century, with the English school of the seventeenth century and the physiology of respiration, with the physiology of digestion in the eighteenth century, with the modern doctrines of respiration and Black, Priestley, and Lavoisier, and finally with the older doctrines of the nervous system. The book is one which all should read, and it is beautifully printed and of a most convenient size. We have noted only two misprints, one of which is on p. 136—namely, "nimium" instead of "minium," an instance of a commonly occurring error both in MSS. and in typography; there are the well-known variant readings in the Te Deum of "fac cum sanctis tuis . . . . numerari," and "fac . . . . cum sanctis . . . . munerari." Perhaps this may explain why the compilers of the Catechism when they wanted to express in a kind of shorthand the words "whatever it may be," put down in answer to the query "What is your name" the expression "N. or M."

Annals of Medical History. Vol. VI., No. 1, March, 1924. New York: Paul B. Hoeber. Pp. 142. $2.50.

DR. Packard, the editor of these Annals, may congratulate himself upon this number which is full of good things. Dr. J. W. Courtney supplies an excellent paper upon that curious member of our profession Dr. Guy Patin, Dean of the Paris Faculty of Medicine. Dr. O. Larsell writes an appreciation of Retzius, the Swedish anatomist and anthropologist. Dr. H. M. Brown gives us a translation of the treatise, De Venenis of Peter of Abano, author of the "Conciliator differentiarum philosophorum," by which work he earned a prosecution for heresy. An interesting paper by Mr. C. E. A. Clayton, librarian to the Manchester Medical Society, upon Peter appeared in The Lancet of April 11th, 1908. The treatise on poisons was first printed at Mantua in 1472, and Dr. Brown deserves the thanks of all those interested in old medical lore for having made it easily accessible, for it is very good reading. Dr. J. F. Ballard reprints a paper read before the Boston Medical History Club in January, 1923, called a Descriptive Outline of the History of Medicine from the Earliest Times to 600 B.C., and Dr. W. R. Steiner supplies a paper upon the Conflict of Medicine with Quackery. We are surprised that he makes no mention of William Clowes, the Elizabethan surgeon, who wrote against quacks and shady practitioners in the most vigorous and uncomplimentary language. An excellent paper is that by Lieut.-Commander W. M. Kerr, of the Medical Corps, U.S.N., on Elisha Kent Kane, M.D., whose name is inseparably connected with that of our own explorer Sir John Franklin, for Kane went upon the Grinnell expedition fitted out by that large-hearted American to search for Franklin in 1850–51, and again in 1853–55, when he was in command. The fate of Franklin was not made clear until McLintock's expedition in the *Fox* (1857), when papers were found in a cairn descriptive of the failure of the expedition and containing an account of Franklin's death in 1848. Editorial articles, correspondence, and reviews conclude an admirable number.

Sexualreform und Sexualwissenschaft.

Edited by Dr. A. Weil. Stuttgart: Julius Püttmann. Pp. 286.

This is a collection of lectures delivered by various medical and legal men at the first international conference on sex matters held at Berlin in 1922. The book illustrates a diversity of views of all aspects of a difficult subject. The English reader will find much that is interesting and sound, but will unhesitatingly reject some of the extreme views expressed.

Psycho-Analysis and Everyman.

By D. N. Barbour. London: George Allen and Unwin. 1923. Pp. 191. 6*s*.

This is a somewhat bald and certainly unconvincing account of psycho-analytic theory, written for the public, and not encroaching upon the domain of medicine. It has the distinction, amongst the flow of similar books, of presenting the subject with no attempt to smooth out the difficulties of accepting the theory, or to fit it into the writer's own pet psychology. In an appendix, however, he gives an interesting and curious explanation of what he calls the myth of the Holy Ghost, in which his personal speculations find free play. The book seems to be a product of reading and contemplation rather than of experience.

Exercise for Health and Correction.

By Frank D. Dickson, M.D., and Rex L. Diveley, M.D., Kansas City, Missouri. London: J. B. Lippincott Company. 1923. Illustrated. Pp. 127. 8*s*. 6*d*.

This little book, which is profusely illustrated by a series of excellent photographs, is intended as a manual of home exercises. From a scientific point of view it leaves very much to be desired, and the claim made on the cover that "this manual is of the greatest value to physical directors [and] doctors . . ." is hardly justified. The statement, for instance, on p. 89, that "the bend is entirely in the pelvis" is one which would not seem to be anatomically correct.

The first section deals with bed exercises, intended primarily for the patient who has been debilitated for some time. The last exercise prescribed is double leg-lifting over the end of a plinth, and is one which, repeated five times, would tax severely even a gymnast in training. Many of the "sitting-up exercises" are less strenuous than some of those described as "bed exercises."

The value of the regular performance of exercises such as those described in this book is well recognised, and, in so far as it stimulates town-dwellers to acquire the habit of doing them, it will serve a useful purpose.

Collected Papers on Beri-Beri.

By H. Fraser, M.D., D.Ph., Deputy Commissioner of Medical Services, Ministry of Pensions; and A. T. Stanford, M.D., M.R.C.P., D.P.H., Director of Government Laboratories, F.M.S. London: John Bale, Sons and Danielsson, Ltd. 1924. Pp. 103. 7*s*. 6*d*.

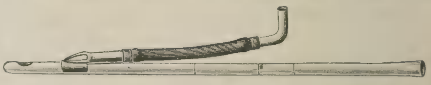
This series of ten papers consists of studies from the Institute for Medical Research of the Federated Malay States carried out by the authors from 1907 onwards. Of these ten papers three have already appeared in The Lancet. The book contains several excellent photographs illustrating experiments, together with coloured illustrations of various samples of rice-grain as seen under the microscope. These collected papers form the seventeenth publication in a series of studies made at the Institute, and they have been reprinted without alteration from their original form. The usefulness of the compilation, however, might have been increased by the inclusion of a general index. Concurrently with the authors' work biochemical research in Europe and America has done much to solve the problem of deficiency disease; and beri-beri, at least, is well on the way to extinction.

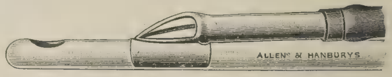
Dr. W. C. Rivers's "Sexuological Essays" (reviewed in The Lancet last week) can be obtained from the author, Worsboro' Bridge, Barnsley.

New Inventions.

AN EXPIRATORY ATTACHMENT FOR ENDOTRACHEAL CATHETERS.

The value of adequate provision for expiration in endotracheal insufflation anæsthesia has already been referred to by me in The Lancet (1923, ii., 228). The metal appliance here illustrated is the outcome of further experiment, and has proved particularly useful in the case of children in whom the glottis will not accommodate an expiratory rubber tube of sufficient calibre at the same time as a catheter. A series of five sizes has been constructed for attachment respectively to catheters Nos. 23, 20, 16, 13, and 9 (French). A special catheter with a maximum calibre has been made to fit the smallest tube. The metal clip which holds the catheter is split longitudinally and is composed of metal which combines to a certain extent the qualities of malleability and resiliency. Some adjustment is therefore possible and necessary, as catheters of different makes may vary slightly in a given size. The expiratory attachment is connected, as shown, with a piece of rubber tubing. At the point where the latter reaches the teeth the addition of a metal elbow prevents the catheter from being bitten and at the same time directs the expiration away from the surgeon.





The tubes and special No. 9 F. catheter are made by Messrs. Allen and Hanburys, of Wigmore-street, London, W.

LONDON: SATURDAY, JUNE 28, 1924.

THE CROONIAN LECTURES.

THE comprehensive summary of what is known about leprosy, which Sir LEONARD ROGERS has just enunciated in the first two of his four Croonian lectures to the Royal College of Physicians of London, will be accepted as authoritative. In the first he traced the history of this disease from the earliest reliable record of its appearance in Europe over a thousand years ago to its present widespread distribution. A discussion of the general conditions influencing the prevalence of leprosy and an account of the difficulties experienced, even after the isolation of the causative bacillus, in proving its communicability formed the concluding sections of this lecture. In the second lecture Sir LEONARD ROGERS considered the possible modes of infection in some detail, and suggested a plausible explanation for the acknowledged relation between its incidence and conditions of high humidity and temperature; this relation affords a good basis for the study of the prophylactic measures which he next elaborated. The third lecture was devoted to the treatment of established leprosy and dealt chiefly with the efforts made by the lecturer to search for more efficient preparations derived from chaulmoogra and allied oils long reputed of benefit in leprosy, and with the experimental grounds for his hopes that these may prove curative.

Sir LEONARD ROGERS admits that it is still too early to allow of anything like final conclusions regarding the precise value of the treatment of leprosy by sodium gynocardate and sodium morrhuate, but he claims, with justice, that the results of extensive trials in various settlements are encouraging. In the fourth Croonian lecture, which we publish in full in this issue of THE LANCET, the lecturer raises the question of the possible application of the new line of treatment to tuberculosis, on the basis that if the *B. lepræ* is destroyed by intravenous injections of gynocardates, there is some hope of inducing a similar change in another bacillus belonging to the acid-fast group. While sharing the lecturer's hopes and indeed appreciating that we may at last be setting out, under his guidance, on the right road of attack against tuberculosis, a word of caution must be said. The distress caused to sufferers and their friends from over-confidence in the possibilities of any remedy must be set against the desire, by eager praise, to encourage investigators to press forward on paths showing any foundation for hope.

Sir LEONARD ROGERS gives with scrupulous fairness the case for and against optimism and confesses freely that the experimental basis of his hopes is not unchallenged. In the recently published annual report of the Lister Institute mention is made of some attempts to test the claim that the sodium salts of various fatty acids exert a favourable and healing action in tuberculosis, in view of their action on the tubercle bacillus. The selective action of fatty acids on acid-fast bacilli is acknowledged to be striking, but investigation of the potency of a number of these acids in this respect did not indicate any marked differences between them except in the case of chaulmoogra oil derivatives, which had a decidedly greater effect in inhibiting the growth of cultures of *B. tuberculosis* than the derivatives of any other acids tested, including acids derived from cod-liver oil. Clinically, however, there is a good deal to suggest that injections of sodium morrhuate may have a specific healing action on tuberculous lesions, and, at any rate, Sir LEONARD ROGERS appears to have made out a sound case for more extensive trials of this remedy.

◆

THE FEDERATION OF MEDICAL AND ALLIED SERVICES.

THERE will be found in another column an account of the annual dinner of the Federation of Medical and Allied Services which was held on Friday last, June 20th, under the presidency of Sir BERKELEY MOYNIHAN. The occasion must have been a stimulating one for those concerned in the welfare of the Federation, owing to the high quarters from which they received assurances that their work should be very valuable both to the public and to those who have the charge of the health of that public. It is quite clear that persons in responsible positions are now realising that an alliance between medicine and its allied services with the public in the interests of public health contains vast possibilities for national good; it has, indeed, become necessary to the cause of national health. To render all help in forming and cementing this alliance is the programme of the Federation, which thus is placed in the gratifying position of filling a national need. No less than this was said of the Federation by more than one speaker at the feast.

But some of the kind words in which this sentiment was conveyed may possibly have been, if stimulating, also embarrassing for those who have the policy of the Federation in their direction, and for a reason which they will admit. Although a certain amount of good and practical work in various directions, most of which have been indicated before now in these columns, has been performed by the Federation, there can be no doubt that what it has done is but a small fraction of what it was assured last week by the present Minister of Health and by his predecessor was expected of it. In the life of all young bodies the position is constantly reached when aims are not balanced by performances, while the public support that would make success certain is withheld until that success, if possible, has been achieved without the public support. Of the useful and even great things which such a body as the Federation might do, acting as a liaison now between the public and the medical profession, and now between the public and national authority, few, if any, can be brought to practical issue without the public coöperation, and the recent beginning of such coöperation is by far the most promising thing in the affairs of the Federation. And by coöperation is not meant subsidy, but rather a willingness to serve. Sir THOMAS HORDER, chairman of the executive committee of the Federation, in a short sentence in a short speech, probably said all there is to be said on this position when he urged upon members of the Federation, medical and lay, the necessity at the present juncture for individual work.

Ministers of Health have come and have gone with great rapidity since the high office was first instituted, but it is worth remembering that during the short life of the Federation not less than five of them have personally welcomed the idea of a combined body which would be able to place before them the considered views of medicine, pharmacy, nursing, and the kindred activities. To some extent members of the public have endorsed the view expressed by these Ministers by giving their adherence to the Federation and forming a Citizens' Council. The result of this is that the Federation possesses within its organisation a body of men capable of meeting together and expressing by their joint deliberations views on the health of the people which could not fail to be valuable to the country; but the opportunity of expressing these views has not yet arisen in any frequent or important manner. Sir Thomas Horder has, we think, exactly indicated what is required—namely, the desirability of some individual activity by the Federation which will lead to a demand for its services both from the authorities and from the public. If when that demand comes it is met satisfactorily, the Federation need have no fear of receiving wide support from varied sources. Why should not the Citizens' Council set the Federation a definite task and underwrite the reasonable expenses in connexion with the work? All would gain by such a course, and any expenditure would be balanced and overbalanced by the economy in life resulting from the advice. The Minister of Health, at the dinner of the Federation, gave his hearers an apposite lead when he indicated the waste due to the employment of unsuitable persons in particular occupations. The big employer who should call in the Federation to assist him here would be a veritable pioneer in the cause of national health.

RABBIT FEVER.

It is an old maxim that no one is likely to diagnose a disease of which he has not heard. This has often become evident when a disease hitherto unrecognised by the profession is first described and defined. As soon as this has been clearly and convincingly done it is apt to turn out that the "new disease" is not literally "new" at all, and has, perhaps, long been recognised under various names in different localities. Such appears to be the case with the infective disease in man to which the name of "tularæmia" was given by Edward Francis of Washington in 1922. The infecting micro-organism was then shown by him to be identical with the *Bacterium tularense* described by McCoy and Chapin in 1912 as the cause of a fatal plague-like disease of the ground-squirrel (*Citellus mollis*) in Tulare County, California. The bacillus is very minute, 0·2 to 0·3 by 0·3 to 6·0 microns in diameter, and is found in the blood and in enormous masses in the organs of diseased animals, especially in the liver and spleen of inoculated mice. In cultures which can be obtained on special nutrient agar containing egg or cystin the bacilli are slightly larger. There seems to be little doubt that six human cases following bites of horse-flies described by Pearse in Brigham City, Utah, in 1911, were the same disease, and Francis has collected 100 cases from the same district. It has now been recognised in at least ten States of the Union, including places on both the eastern and western seaboard. Moreover, evidence of the disease appears to be not uncommon in rabbits brought for sale to Washington market, and human infection is known amongst the market men by whom it is vulgarly called "rabbit fever." One of the cases recorded by Francis in 1923 had apparently contracted the disease in the market by handling dead rabbits, and the patient volunteered the diagnosis. The first human cases shown to be due to *B. tularense* were suffering from a form of illness, known locally as "deer-fly fever," occurring amongst harvesters in Utah. They were probably infected by the bite of a species of *Chrysops* which transmits the disease from the "jack-rabbit" to man. More than one species of wild rodent is known to be naturally subject to the disease; the name "jack-rabbit" is given to several species of *Lepus*, and in addition the ground-squirrel and the "cotton-tail" *Lepus sylvestris*, which is commonly sold in the Washington market, are liable to the disease in the wild state.

Experimentally it has been found that the disease can be passed from rabbit to rabbit or guinea-pig by the bed-bug, by fleas, lice, and a species of mite. Infection takes place in animals very readily through the shaved skin, and in man the conjunctiva, perhaps mucous membranes and abrasions of the skin may also be sites of entry. So infectious is tularæmia for human beings that at Washington all the laboratory workers who were occupied with investigating the disease—six in number—became infected, and one or two of them contracted second attacks. The point where the infection enters may be the seat of a slough, but this is not always the case and no lesions may be found. The clinical course is characterised at the onset by irregular fever, which at times may reach 104° F., and by enlargement of lymphatic glands, and later by a long period of debility with slight febrile disturbance causing incapacity for any serious work, whether physical or mental. The fever may be continuously so high as to simulate enterica, but severe pains or headache are unusual. A moderate leucocytosis of 12,000 to 14,000 is the rule. The only known cases outside the United States have been those of three laboratory workers in London who were studying cultures obtained from Washington by means of animal experiments and in other ways.

Very few fatal cases are known to have occurred, but recently Dr. J. Russell Verbrycke has recorded[1] the first post-mortem examination on a human case of tularæmia in a woman of 67. A diagnosis of gall-stones and inflammation of the gall-bladder was made, and jaundice was present during the first week of illness. On the twelfth day from the onset the abdomen was opened, but no further operation was performed. Death occurred six days later. The infection in this case was no doubt contracted whilst preparing and cooking a rabbit five days before the onset, which agrees with an incubation period of about four days which had been observed in previous cases. Post mortem, the pleural cavities both contained cloudy yellowish fluid, and the lower portions of both lungs were covered with greenish-yellow lymph. Irregular, hard, discrete nodules were found throughout the lower lobes of the left lung. The liver was soft and bile-stained; the spleen large and very soft, and in its substance were many very small yellowish-white nodules, which closely resembled the nodules found in the livers of rabbits dead of tularæmia. No tubercle bacilli could be detected in the nodules in the lungs or spleen. Guinea-pigs and two rabbits inoculated from the spleen died and showed the speckling of the liver and spleen with small necrotic areas characteristic of the disease. The diagnosis in this fatal case, as also in about 20 other cases which have been observed clinically, was confirmed by agglutination of a formolised emulsion of the bacteria by the patient's serum. A positive agglutination result is to be expected about 14 days after the onset and appears to be highly specific. The usual titre reached with patient's serum is 1/100 or more, whereas control serum from other persons gives a negative result in a dilution of 1/10.

Tularæmia is therefore a widespread and serious disease of man in the United States of America, which is spread from wild rabbits to man by the bites of blood-sucking insects and also by the handling of dead animals in the market or kitchen. Its diagnosis may easily be missed, but its natural occurrence in other countries is as yet unknown.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND: AN AFTERNOON RECEPTION.

THERE will be a meeting of the Fellows of the College on Thursday, July 3rd, at 10 A.M., for the election of three Fellows into the Council, in the vacancies occasioned by the retirement in rotation of Mr. W. F. Haslam, Mr. T. H. Openshaw, and Mr. Raymond Johnson. For these three vacancies there are 11 candidates—namely, Mr. W. McAdam Eccles (formerly a member of the Council), Mr. W. E. Miles, Mr. H. J. Paterson, Mr. T. P. Legg, Mr. A. H. Burgess, Mr. Victor Bonney, Mr. Wilfred Trotter, Mr. Philip Turner, Sir Charles Gordon-Watson, Mr. Hugh Lett, and Mr. G. Grey Turner. The voting papers went out to the constituencies at the end of April and must be returned not later than the morning of July 3rd.

The President and Council of the College have issued invitations to a reception at the College on the same day, when the annual exhibition of additions to the museum will be opened for inspection between the hours of 4 and 6 P.M. Cards of invitation are not required by the Fellows. In making these arrangements, the Council is reverting to a custom which was highly successful when Fellows of the College had to attend in person to record their votes. They not only attended to vote, but made a point of examining the various dissections and preparations placed on exhibition in the Council room. As very few Fellows now record their vote in person it was decided, a few years since, to hold the annual exhibition in October instead of July. By the special arrangements now made it is hoped that the annual exhibition will recover its former popularity, and that July 3rd will not only be "Election Day" for the Council but "Museum Day" for the College. On the present occasion many specimens of surgical, pathological, and anthropological interest will be on show. The additions and other selected preparations will form a special exhibit in the museum until the end of August.

DOMESTIC GAS LEAKAGE.

A REPORT of the joint committee of the Society of Medical Officers of Health and the Royal Sanitary Institute on flueless gas stoves, which has been referred to already in our columns, brings to the fore the whole question of defective gas fittings. Perhaps there is no better exemplification of the truth of the proverb that "Familiarity breeds contempt" than the carelessness of gas consumers and gas vendors as to the state of the fittings used for the supply of a useful product with deadly qualities. Do the lessons supplied by inquest after inquest convey no messages to gas companies, to plumbers, or to householders? Ground air and drain air may have been unduly blamed in the past, but the scare about these has helped us to get rid of leaky cesspools in the neighbourhood of dwellings, and to secure well-laid drains for the speedy removal of excreta and foul liquids. And, be it remembered, that here the noxious influences attributed to sewer air were certainly exaggerated. Coal-gas is much more poisonous than is the ground or drain air, but despite the sinister popularity with suicides its use has aroused no such scare. We do not want to renew the air-supply of our dwellings from drains or ground air, but we seem indifferent to gross chances of inhaling coal-gas.

Dr. E. B. Hazleton read a paper at the last meeting of the British Medical Association[1] which went to show that there was some leakage from most of the taps fixed, as they ordinarily are, on the bottom side of gas brackets, and that it was quite common to find in the morning in ill-ventilated bedrooms with such fittings carbonic monoxide present to the extent of 0·01 to 0·02 per cent. Dr. J. S. Owens's report shows that a man who breathes an atmosphere containing 0·2 per cent. of CO for four or five hours will usually die. One has therefore no difficulty in believing with Dr. Hazleton that if a man breathes night after night an atmosphere containing 1/10 or 1/20 of this amount of CO, the effects on his health may be quite serious. Dr. Hazleton's remedies are to abolish gas lighting for bedrooms and alternatively to have the tap fixed on the top of the bracket, by which plan the tap is kept by the force of gravity more or less gas-tight. Most domestic gas meters have, we believe, a clock face, one revolution of which indicates the passing of 5 cubic feet of gas, but how many householders take the trouble to use this check to leakage. One of our correspondents has had the curiosity to apply this test. He was only using gas for heating and cooking, and he found that the gas which passed the meter during the night, when no gas was being burnt, amounted to 1·4 cubic feet. His own sense of smell was poor, but his wife's was good, and she thought she smelt gas in two places. An employee of the gas company took in hand the two gas fires which seemed indicated as the sources of the leakage, which on the next night was reduced to 0·6 cubic feet. This last-named leakage appeared to be due to the failure to turn off the stop-tap of the gas cooking stove, the numerous fittings of which were evidently leaky. Except for the meter, the gas company in question possessed no apparatus for testing the tightness of the gas fittings. If the meter had still indicated a leak, they had no means for locating it.

The supply of gas is a monopoly whether it belong to a company or a local authority, and it is only reasonable that the monopolist should be in a position to guarantee the fittings by which he supplies his wares. Unfortunately, gas and water are in a different position. The water department loses by leakage, the gas department is paid at the same rate for leakages as for legitimately used gas. The competition with electricity should be, however, sufficient incentive to the gas companies to take steps to prevent their customers being poisoned. Further, the extended use of gas is one of the planks in the smoke prevention programme. The acuteness of the olfactory sense is so notoriously variable as to constitute a very feeble line of defence against coal-gas poisoning. On every ground, then, and in the interests of both vendors and consumers, we think gas departments and companies should take steps to see that only fittings of a safe type are in use, and further, that they are in a position to test, on application and in return for payment of a reasonable fee, the fittings of any customer and inform him as to whether such fittings are gas-tight and in all respects satisfactory.

ACUTE PYOGENIC PAROTITIS AND ITS DIAGNOSIS.

IN a paper by Dr. R. G. Spurling and Dr. F. W. Stewart in the *Boston Medical and Surgical Journal* for May 15th, attention is drawn to the not rare occurrence of acute pyogenic parotitis in otherwise healthy persons and to the valuable information to be obtained by catheterisation of Stenson's duct in obscure cases of swellings in the parotid region. Among 22 cases of suppurative parotitis observed during the past five years in the authors' hospital, there were four distinguished by the fact that the patients had seemingly been quite well up to the time of the first appearance of a swelling in the parotid region. Three of these cases occurred within two months—a grouping suggestive of some common cause. The authors confess to ignorance of this cause by labelling these cases as "idiopathic." With regard to the diagnosis of such unilateral swellings, they have come to the conclusion that the simplest method of differentiating pyogenic from non-pyogenic parotitis and other morbid conditions in the parotid region is to catheterise the parotid duct so as to secure material for culture and microscopic examination. Such catheterisation has been employed in the past in the course of experimental work on parotitis, but as a means of clinical diagnosis it has been much neglected. The contents of the parotid duct may not always be sterile even in health, and a positive culture obtained from this duct is therefore not an infallible sign of pyogenic parotitis. But a pure culture of such a germ as the *Streptococcus viridans* is undoubtedly of great diagnostic value, particularly if it is obtained on several occasions. The presence of pus cells in the catheter specimen is, in the authors' opinion, almost pathognomonic of infection of the parotid gland. Their procedure is simple. The catheter can be easily extemporised with a piece of glass tubing, one end of which is drawn out into a capillary tube about one millimetre in diameter, while the other end is fitted with a rubber aspirating bulb. It will often be sufficient to note whether or not the opening of the duct is inflamed and gaping, pus escaping from it when pressure is exerted on the duct and gland from without. In doubtful cases the introduction of the glass tube into the duct and the aspiration of a little of its contents for a bacteriological examination should materially help towards a correct diagnosis. The introduction of the tube is facilitated if the ampulla of the duct is inflamed. The authors conclude that failure to examine closely the parotid duct is responsible for the majority of errors. They recommend that in every swelling of the face and neck in the region of the ear a possibility of septic parotitis should be considered seriously and a careful examination of Stenson's duct should be made.

---

PARENCHYMATOUS KERATITIS.

THE first of the monographs published in connexion with the *British Journal of Ophthalmology*, which are to be sold at a cheaper rate to subscribers to that publication, is an authoritative work on parenchymatous keratitis.[1] Although the main facts about the disease and its dependence on congenital syphilis were established by Jonathan Hutchinson more than 60 years ago, there are several matters connected with it on which ophthalmologists are not even yet in complete agreement. Mr. Holmes Spicer has made a special study of the subject for many years and this monograph, based on an examination of nearly 700 cases, is an embodiment of his conclusions.

It is universally acknowledged that the principal cause of the disease is congenital syphilis. In this series of cases either other signs of syphilis were present or a family history was obtained in 70 per cent. In the remainder there was no mention of family history or other signs, but this does not necessarily preclude the presence of syphilis. The teeth were typical or suggestive in 44 per cent. Acquired syphilis, to the exclusion of the congenital form, was found in 3·3 per cent. of the cases, more commonly in women than in men. With regard to tubercle its influence in producing typical interstitial keratitis is disputable, says the author. Mixed infections, of course, occur.

The most original part of the essay concerns the various forms of corneal opacity which are characteristic of the disease. Several figures illustrate the subject. Specially noteworthy are those of striate opacities caused by the folding of the posterior surface of the cornea, and of the curious forms sometimes assumed by the deposits, formerly called "keratitis punctata," but better "K.P.," which may be considered to stand for the more accurate description, "keratic precipitates." With regard to the age of onset, in 80 per cent. of Mr. Spicer's cases it was between 5 and 25, but a first attack sometimes occurs both at an earlier and a later age. There were three cases of infantile syphilis in which definite interstitial keratitis was present at birth, and in one case a typical first attack occurred in a man of 40 with scars of old choroiditis, so that in all probability the spirochæte had been lying latent in the cornea for 40 years. The interval between the attack in one eye and its fellow was in three-quarters of the cases less than a year, but there were many cases with much longer intervals. Two per cent. showed an interval of more than five years. The longest interval recorded was 26 years.

As to the relation between interstitial keratitis and injury, it has been maintained by Harrison Butler that this relation exists in as high a proportion as 20 per cent., an association which, if it could be established, would be of great importance in view of claims for compensation. A history of injury, however, can often be found if it is looked for, without the true relation being anything more than accidental, and Mr. Spicer agrees with most authorities in putting the true ratio in which an injury had an important influence in determining an attack in an eye predisposed to the disease at not more than about 3 per cent. With regard to relapses, they occurred in 9 per cent. of the cases, in one case as much as 30 years after the first attack, the probable cause being that the cornea was incompletely scavenged by leucocytes in the primary attack. A question of some interest is whether or not inherited syphilis confers immunity to the acquired disease. As a rule no doubt it does, but there are instances of patients with interstitial keratitis where it did not. According to our present knowledge, the *Spirochæta pallida* is the cause of the attack. Though it has not been found in the human cornea, it has been found experimentally in the cornea of monkeys. A certain number of cases occur, however, in which syphilis can be excluded. These cases are generally called by a different name—"keratitis profunda." They often occur in middle-aged men addicted to alcohol; generally, only one eye is affected, and the disease runs a comparatively mild course.

As to treatment, the author decidedly inclines to conservative methods. He even warns us against using too much atropine on the ground that atropine irritation is not infrequent. Injections with the arsenical compounds he reserves for severe cases where there is much irritability of the eye and in which the general condition of the patient calls for it. The greatest importance is attached to measures calculated to improve the general health, for which reason a stay in hospital is often attended by the best possible results. In minimising the importance of direct anti-syphilitic treatment the writer runs counter to considerable recent opinion.

COPPER AND BRASS IN HOUSEHOLD WATER SERVICES.

EVERY householder from time to time has trouble with his water-supply. If the water is hard deposits form in the kettles and boilers and hot-water pipes; if very soft the water may act upon the material of which the service pipes are constructed, the water may become tinted and discoloured by the iron taken up and deposited, or zinc or lead may be taken into solution, and in the latter case there is serious danger of injury to health. The Copper and Brass Extended Uses Council has recently issued a "Treatise" for the information of water authorities, engineers, architects, builders, plumbers, and all interested in houses and house construction, in which they assert that practically all these troubles can be avoided if copper and brass only are used in the interior water fittings, boilers, tanks, pipes, &c., and they also contend that the cost is only a little over that of lead, and only from 18 to 38 per cent. more than iron, and that when the upkeep is taken into consideration there is an actual economy in the use of copper. Their arguments are very specious, but are well worthy of consideration, especially in districts where soft moorland waters are used; but unfortunately the "Treatise" has been compiled by an engineer and presents the case only from the engineering point of view. No chemist seems to have been consulted with reference to the action of water on such pipes, nor has the view of any medical authority been obtained on the aspect from the health point of view, a course which is suggested by their admission that acid moorland waters do act upon copper. Moreover, the few words said about the action of water on lead and copper requires revision by the chemist. It is stated that "Lead is itself easily oxidised, and the oxide in general forms a protective coating. It is the organic acids in the plumbo-solvent water which, dissolving the layer of lead oxide, subjects the metal to successive attacks. Copper corrodes little, and, so far as it does, the product is protective." These statements, to say the least, require confirmation, and unless they can be confirmed, which is doubtful, the evidence from the chemical and medical point of view has no value. The Council would be well advised to give this matter its serious attention, as the subject is one of very great importance. No reference is made to the use of tinned copper pipes, save to say that the tin used to line such pipes often contains lead. This used to be the case, but it is alleged that the difficulty of coating the copper with tin free from lead has been surmounted. If such is the case tinned pipes would appear to be preferable to copper. The use of copper alone, as suggested, does not appear to have as yet received any practical trial, and such a trial with waters of various types is absolutely essential before their use can be recommended with confidence.

MICROSPORIDIA AS THE CAUSE OF RABIES.

THE ætiological agent of rabies has been the subject of numerous researches, and several claimants are in the field without any one of them being generally accepted at the present time. The latest suggestion is that of Y. Manouelian and J. Viala,[1] who describe a protozoon of the microsporidia genus in the tissues of affected subjects. The possibility of a protozoal parasite was long ago suggested, and the question whether the well-known Negri bodies, small corpuscular formations found within the cells of the nervous system, especially in the large cells of the hippocampal region, are to be looked upon as protozoa, which is the view of many authorities, or merely as post hoc degeneration products of the diseased cell, which is perhaps the more favoured view, has not yet been definitely settled. The findings of Manouelian and Viala undoubtedly have their origin in the disputes which have arisen over the causation of lethargic encephalitis. Discordant findings in the experimental investigation of this disease in rabbits has led to the discovery of the existence of a spontaneous form of encephalitis in the rabbit, whose existence was first described in this country by F. W. Twort. C. Levaditi, whose positive results with human encephalitis material have been at variance with the results of C. Kling, H. Davide, and F. Liljenquist in Sweden, investigated the lesions in the rabbit's brain in the spontaneous disease, and has described the formation of small spore-containing cysts of a parasite which he has named *Encephalitozoon cuniculi*. The step from these findings to the suggestion that a like cause may operate in so similar a disease as rabies is a short one, and such a suggestion was actually made by Levaditi soon after the description and figuring of the parasite we have just mentioned. He put forward the view that the Negri bodies are spore-containing cysts which represent only one phase in the life-history of a protozoal parasite of which the individual units are, at another stage, so minute as to be ultra-microscopic and filtrable. Failure adequately to observe the intimate structure of the Negri bodies is, in his opinion, due to the impermeability of the capsule to chromatin stains, a property which can be modified by the use of acid fixatives. This suggestion has apparently borne fruit in the work of the two French investigators, which has appeared in a recent number of the *Annales de l'Institut Pasteur.* By the use of a special technique, which involves the employment of an acid-fixing solution, they have demonstrated the presence of small elongated or oval bodies, occurring in various parts of the nervous system, both accompanying and appearing independent of the Negri bodies, which they resemble in being usually intracellular, but in size are very much smaller. The figured appearances of these "parasites" is very striking, as is also their similarity to the bodies described by Levaditi in the encephalitis of rabbits to which we have just alluded. The relationship of the newly described formations to the Negri bodies is not clear, the authors of the present paper considering the latter to consist of accumulated and degenerated masses of the smaller parasite. The parasites are also described as being present in the salivary glands. It is not possible to pronounce any definite opinion upon this interesting piece of work, but, whilst waiting for further results, it may be pointed out that the newly described parasite does not in any way appear to resemble bodies figured by Noguchi in 1913, which he then claimed to have cultivated by the special technique associated with his name and suggested as the causal factor of rabies. It is also interesting to note that on that occasion the claim was associated with the then prominent investigations upon poliomyelitis, whilst the present one comes obviously in the train of the investigation of encephalitis.

THE STORY OF "SAY NINETY-NINE."

ON June 24th Sir William Hale-White, as President of the Royal Society of Medicine, and Lady Hale-White received the guests at a social evening, given by the Society to welcome medical men from overseas now in London. After cordially greeting the overseas visitors the President proceeded to give a short address on the history of percussion and auscultation. He pointed out that nothing that doctors do has seized the popular imagination more than their habit of tapping the chest and listening to it with a stethoscope, to learn whether the sounds of breathing and of the heart are natural and whether the patient's voice is properly conducted. In the "Mystery of Edwin Drood," Durdles, from tapping a slab, concludes that under it is an "old 'un crumbled away in a stone coffin." In Kipling's "Marklake Witches" is a description of how Jerry listened with a wooden toy trumpet to Rene's chest. Wendell Holmes relates what happened from using a stethoscope with a fly in it. The pages of *Punch* contain many pictures in which the stethoscope appears. By noting how his spoken voice is carried through the chest by a stethoscope to the trained ear a physician can obtain further evidence confirmatory of the percussion findings as to whether a patient's chest contains air, solid, or fluid. Since the words "ninety-nine" are produced in the larynx they are most suitable for this purpose and this phrase has become very popular. There exist "Say Ninety-nine" cough lozenges, "Say Ninety-nine" stays and "Say Ninety-nine" boots; jokes about "Say Ninety-nine" are common on the stage and in comic papers. Sir William Hale-White recalled the fact that Auenbrugger was the first, in a little Latin book containing only 7000 words, published in 1761, to teach what may be learned from percussing the chest. He recorded that the chest of a healthy person yields a note resembling the stifled sound of a drum covered with a thick cloth. He explained also how to strike it to obtain the best results, and discussed the varying note at different parts of the chest and the differences of note according as the chest contains air, solid, or fluid. Auenbrugger's work remained unnoticed until in 1788 Corvisart began to practise the method and in 1808 published a translation of Auenbrugger's book. Fortunately Laennec, who was born at Quimper in 1781, studied under Corvisart and it was to him that the introduction of percussion in medicine was chiefly due. He lived at Nantes with his uncle, William Laennec, who superintended his education in medicine at the hospital there, protecting him from the horrors of the Revolution and the parsimony of his niggardly father. He left for Paris in 1801 and continued his medical studies there, taking his degree in 1804. He lectured constantly on morbid anatomy, which subject he was the first to raise to a science; he not only gave admirable descriptions, but correlated the conditions found after death with the signs and symptoms observed during life. In spite of wretched health and many family troubles he worked extraordinarily hard, conducting a large fashionable practice, studying languages, making post-mortems, and lecturing to those who came from all over the world to hear him. In 1816 he announced his discovery that it was possible to listen to the chest with a stethoscope. In August, 1819, he published his famous "De l'Auscultation Médiate," containing precise and original descriptions of clinical symptoms and post-mortem appearances. Many of these referred to conditions previously unknown, of which the most celebrated was his demonstration that tubercle is a new formation, and that phthisis is tuberculous. Laennec described all the multitude of physical signs that may be recognised with the stethoscope, and in his first chapter explained what may be learned from listening with the stethoscope on the chest to the patient's spoken voice. From this chapter in this book arose our practice of telling the patient to say ninety-nine. Sir William Hale-White illustrated an absorbing account of the story of Laennec's life with many pictures of the scenes among which this great doctor worked, lived, and died.

A HOME FOR CHILDREN WITH RHEUMATIC HEART DISEASE.

Kurandai, Hartfield, Sussex, was opened three months ago by the Invalid Children's Aid Association as a home for children suffering from rheumatic affections of the heart, boys being taken up to 7 and girls up to 14 years of age. There are three main open-air wards, two facing south, in which the children's beds are placed, each ward having its own bathrooms attached. The whole front of the sheds is open to the garden, but some shelter can be secured on that side, when necessary, by means of shutters. There are also two small rooms on the ground floor of the house with large windows. The children receive regular education by two trained teachers, and their games and exercise are arranged according to their capacity. The nursing staff consists of the matron, a sister, and six nurses. Fifty children can be taken and 48 are actually in residence, including a few cases of chorea. A garden party was given at Kurandai by the I.C.A.A. on June 21st, when Sir John Broadbent explained lucidly to the assembly the need for such a home. He pointed out that rheumatism was very prevalent in this country, and that in childhood it attacked the heart rather than the joints, giving rise to lesions of the valves and muscular walls of the heart. Lesions of the valves impaired the mechanism of the heart as a pump, and certain changes took place in the cavities and walls of the heart which were in part an effort by Nature to counteract and overcome the difficulties entailed by the valvular lesion. For the development of these changes a long period of time was often necessary, during which the child should be kept more or less at rest and under supervision. Even more important was the injury to the muscular wall of the heart, which might result from rheumatism, as this damaged the propulsive mechanism. As a result of rheumatic pericarditis the tonicity of the heart-muscle might be greatly impaired, so that it resembled perished rubber and gave way under the strain of its ordinary work; hence ensued great dilatation of all the cavities of the heart and symptoms of heart failure. Recovery was common even in serious cases, but it was obvious that patients could not be kept in a busy general hospital for the many months of rest required, and if they returned home they might be seriously and unnecessarily handicapped for the rest of their life for want of skilled care. In this new home patients could be kept for several months if necessary, and would be regularly visited by Dr. J. W. Prince, of Hartfield; periodically by a member of the consulting staff.

Proof of the value to fitting cases of such a home is afforded by the encouraging results obtained at the Edgar Lee Home, Stonebridge Park. This is a home founded for boys with rheumatic heart disease by the Invalid Children's Aid Association in 1918. Since its inception 327 cases have been admitted. The boys on leaving are advised as to the nature of the work they can safely undertake, and the Association endeavours to keep in touch with them afterwards. At a medical inspection last year of some of those who had passed through the home, of 39 boys only three were considered to require further treatment. Dr. F. J. Poynton, who also spoke to the guests of the I.C.A.A. at Kurandai, pointed out that children with rheumatic heart disease are unsuitable for the ordinary convalescent home where children are recovering from some surgical operation or minor illness. They are high strung, and the damaged heart requires much care. Those without special opportunities for investigation have not the slightest conception of the frequency of rheumatic heart disease. Dr. Poynton noted that of 140 deaths at the Hospital for Sick Children, Great Ormond-street, from heart disease, 90 were due to rheumatism and all were in children under 12 years. It was not, however, the fatal cases and the totally incapacitated children that this home would help, but those cases who had passed through one or more attacks and had, as a result, hearts weakened or permanently damaged in slight degree. These children, he said, could lead useful, if restricted, lives provided they were given time to get strong hearts, that their hearts were tested by gradual increase in physical exercise, and their education continued. They should return to their homes with an indication as to their physical capacities, and report to their hospitals or medical supervisors. At this home the object would be to train hearts to renewed health and strength, to keep minds active and happy, to increase our knowledge of the power of the heart for recuperation, to learn more of the life-history of rheumatic heart disease, and to take a practical and living part in the national study of the prevention of rheumatism and its complications.

THE ROYAL SOCIETY CONVERSAZIONE.

A CONVERSAZIONE was held at Burlington House on June 18th, when Sir Charles Sherrington, the President, and Lady Sherrington received a numerous company. Many interesting exhibits were shown, and during the evening Prof. Lucien Bull, of the Marey Institute, Paris, gave two demonstrations of recent developments in high-speed cinematography. His beautiful slow films illustrating the flight of birds, and the equally graceful movements of a dancer, gave great pleasure. Among the exhibits Captain C. Diver and Prof. A. E. Boycott, F.R.S., demonstrated the results of breeding experiments with the snail *Limnœa peregra*. Whereas most snails are typically coiled in a right-handed spiral, occasionally left-handed examples are found. Breeding from a sinistral race of these animals records have been obtained for some 600 families (about 53,000 snails), and it is apparent that a definite system of inheritance is being followed. Dr. T. S. P. Strangeways, Dr. R. G. Canti, Dr. M. Donaldson, and Dr. F. G. Hopwood demonstrated living cells growing in vitro under the influence of radium. The internal cytological structure was displayed by the use of dark-ground illumination. A large collection of permanent tissue-culture preparations, illustrating the effect of exposure to X rays upon the different phases of mitosis, was also shown by Dr. Strangeways. Sir Almroth Wright, Mr. A. Fleming, and Dr. L. Colebrook demonstrated new methods for the exploration of bacterial disease, and for the study of the effects of treatment. The preparations shown illustrated the new technique which Wright and his colleagues have elaborated in recent years. Mr. A. Eidenow, Dr. Leonard Hill, F.R.S., and Mr. A. Webster showed a method of measuring ultra-violet radiation. It consists in the determination of the degree of bleaching brought about in a solution of acetone and methylene-blue contained in standard quartz tubes.

A Royal Commission has been appointed to inquire into the existing law and administrative machinery in connexion with the certification, detention, and care of people who are, or are alleged to be, of unsound mind. The Commission will consider the question of the treatment of mental disorder without certification, and has the following personnel, experts in lunacy, it will be seen, having been omitted :—The Right Hon. H. P. Macmillan, K.C., Lord Advocate of Scotland (chairman) ; Earl Russell ; Lord Eustace Percy, M.P. ; Sir Thomas Hutchison ; Sir Humphry Rolleston ; Sir Ernest Hiley ; Sir David Drummond ; Mr. W. A. Jowitt, K.C., M.P. ; Mr. F. D. Mackinnon, K.C. ; Mr. H. Snell, M.P. ; Mrs. C. J. Matthew and Miss Madeline Symons. Mr. P. Barter, of the Ministry of Health, will be secretary.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Capt. D. W. Hewitt to be Surg. Rear Admiral.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col and Bt. Col. F. McLennan retires on retd. pay, and is granted the rank of Col.

The undermentioned Lt.-Cols retire on retd. pay : A. D. Jameson, A. R. Greenwood.

R. A. Roth to be temp. Lt. whilst employed as a Dental Surg.

Maj.-Gen. J. R. McMunn, late R.A.M.C., has been apptd. Hon. Surg. to the King, vice Maj.-Gen. E. M. Pilcher, late R.A.M.C., retd. ; and Maj.-Gen. S. F. St.D. Green, late R.A.M.C., has been apptd. Hon. Physician to the King, vice Maj.-Gen. W. W. O. Beveridge, late R.A.M.C., retd.

TERRITORIAL ARMY.

Capt. A. F. Lee to be Major (Prov.).

Lt. E. H. Mayhew to be Capt.

J. Ledingham (late Tank Corps) to be Lt.

Capt. H. J. G. Wells, R.A.M.C., vacates the appointment of Div. Adjt. 49th (W. Riding) Div.

ROYAL AIR FORCE.

F. F. Anslow (temp. Lt. Dental Surgeon, General List, Army) is granted a temporary commission as a Flying Officer, on attachment to the R.A.F.

Squadron Leader H. B. Porteous ceases to be seconded for duty with the South African Air Force.

INDIAN MEDICAL SERVICE.

Capt. H. K. Rowntree to be Major.

Capt. Hem Chandra Barua relinquishes his temporary commission and is permitted to retain the rank of Capt.

DEATHS IN THE SERVICES.

Lt.-Col. B. B. Connolly, C.B., R.A.M.C. (retd.), died on June 20th at Brighton. He qualified with the L.S.A. Lond. in 1869, took the M.R.C.S. Eng. in the following year, and graduated in medicine and surgery at Cambridge in 1891, having been an exhibitioner at Gonville and Caius. He joined the medical department of the Army soon after qualifying, and served with the Jowaki expedition of 1877–78 (medal with clasp) in the South African War, 1879, and with the Egyptian expedition 1882–84. He was present at the battle of Tel-el-Kebir (medal with clasp and bronze star). For his services in the Soudan he was promoted to surg.-maj., and was mentioned in despatches. For services rendered during operations in S. Africa he was promoted to colonel. During the late war he was A.D.M.S. for Sussex.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXVII.—TREATMENT OF CONJUNCTIVITIS.

WITH regard to the treatment of conjunctivitis in general, the following points should be noted. (1) The infectivity of the different forms varies, but the patient should always be advised in bathing the eyes to use small pieces of lint which can be burnt after use, and periodically to boil droppers, eye-cups, &c. (2) The eye should not be covered, as by doing this the secretions are retained and the conjunctival sac is converted into an efficient incubator. (3) Cocaine should not be used to abolish the pain as the effect is only transient, and prolonged use of this drug has a deleterious effect on the cornea. Adrenalin may at times be useful to produce temporary blanching of the conjunctiva, but it should be employed only on special occasions for cosmetic reasons. I have known of cases of chronic catarrhal conjunctivitis perpetuated by the use of this drug, the inflammation ceasing when a simple boric lotion was substituted for the adrenalin. (4) In all cases of ophthalmia neonatorum it is advisable to have a bacteriological examination of a swab from the conjunctiva, and in other cases this should be done when possible before treatment is instituted.

Monocular Conjunctivitis.

Treatment of monocular conjunctivitis with lotion and ointments is usually of little avail, and much valuable time may be lost if a simple examination is not made at the outset. This examination should exclude : (1) Dacrocystitis, by pressing over the lacrymal sac and seeing whether any regurgitation of pus occurs from the lacrymal puncta ; (2) the presence of a foreign body, by everting the lids and inspection of the conjunctival sac, and by examining the cornea with a corneal "loupe" ; (3) the presence of ingrowing lashes by a careful inspection of the lid margin.

Catarrhal Conjunctivitis, Acute and Chronic.

The acute form is usually due to the Koch Weeks's bacillus and epidemic in character, but is sometimes caused by other organisms. Frequent cleansing of the conjunctival sac is essential. This is best effected by warm boric lotion or, if this produces irritation, by warm normal saline. Since the infection is a surface one, it is advisable to hasten the removal of the superficial epithelial cells of the conjunctiva by means of silver nitrate, which is used in a strength of 5 or 10 gr. to the ounce of distilled water, according to the severity of the case. It should never be dropped into the eye for fear of injuring the cornea, but should be painted on the everted palpebral conjunctiva by a wisp of cotton-wool wrapped round a glass rod. Some ophthalmologists neutralise the silver nitrate by subsequent painting with saline ; in practice, however, the amount of sodium chloride in the lacrymal fluid seems sufficient to produce this effect. The applications should not be repeated for 24 hours in order that the conjunctiva may rid itself of the necrosed superficial cells and regenerate the new epithelium. A little bland, unirritating ointment, such as boric vaseline, should be smeared at night along the edges of the lids to prevent their adhesion and allow the muco-purulent discharge to escape. Should the patient be unable to attend daily for silver nitrate, applications of a 10 per cent. solution of argyrol or other organic silver preparation may be ordered for use three or four times daily after the lotion. It is milder than silver nitrate, but since it causes some superficial degeneration, the patient should wash out the argyrol with lotion after it has been in the eyes for three minutes, otherwise small rouleaux of desquamated cells form in the conjunctival sac and may cause considerable discomfort. This washing, moreover, diminishes the liability to argyrosis—i.e., staining of the conjunctiva by the silver. Since this condition if it arises is usually permanent, it is advisable, even with the precaution mentioned above, not to use any silver preparation for longer than three weeks.

Chronic catarrhal conjunctivitis is always a troublesome condition to treat. In the first place, any misplaced eyelashes, lacrymal obstruction, and errors of refraction must be treated. A slightly everted lower lid when the inferior punctum does not drain the lacus lacrymalis may perpetuate the symptoms; it is usually advisable to slit up the duct and remove a small triangular piece of its posterior (conjunctival) wall to avoid the constant epiphora. A plastic operation on the lid may be necessary in some cases. It should be ascertained whether the patient is exposed to irritant vapours, travels often in smoke-laden railway carriages, &c. A careful examination of the upper part of the cornea should be made, in order to exclude pannus, and of the under surface of the upper lid to exclude the presence of a horizontal scar in the subtarsal sulcus. Either of these conditions indicates old trachoma and necessitates a change in treatment. Among local applications, a lotion containing zinc sulphate gr. i., acid boric gr. x. ad ℥ i., is frequently of service. The zinc sulphate may be found more effective if used separately in the form of drops (gr. i. ad ℥ i.) and the boric acid combined with some astringent such as liq. hamamelidis dest. ♏ xxx. ad ℥ i. The conjunctiva may become accustomed to the use of any particular drug, and it is well to have some alternative to the zinc sulphate, such as alum gr. ii. ad ℥ i., or glycerine acid. tannic. ♏ viii. ad ℥ i.

Angular conjunctivitis is a variety of chronic catarrhal conjunctivitis due to the presence of a specific diplobacillus and exhibiting characteristic signs. It yields readily to the use of zinc sulphate drops, gr. ii. ad ℥ i., instilled four times daily, and an ointment such as the following: Ichthyol gr. ii., zinc oxide gr. iii., lanoline ʒ i., vaseline flav. ad ʒ ii., applied to the lids at bed-time. It is very important, however, to correct any errors of refraction, and as relapses are frequent the treatment should continue for a fortnight after all the symptoms have abated.

Purulent Conjunctivitis.

The course of this is modified by the age of the patient, and it is customary to describe that occurring in the new-born child as ophthalmia neonatorum. It is worthy of note that only 60 per cent. of the latter class are gonococcal in origin, the remaining 40 per cent. being pneumococcal, streptococcal, &c.; the last-named types may have just as serious effect on vision as the former. The principal indication in ophthalmia neonatorum is to prevent infection of the cornea and the formation of ulcers. It is not sufficiently well known that St. Margaret's Hospital, Leighton-road, Kentish Town, London, is a special M.A.B. hospital for the treatment of this disease; mothers and babies are taken in together when possible, as children usually do better if breast-feeding is continued. In a bad case the conjunctiva is thoroughly washed out every hour with cold eusol 1 : 7, and a drop of a solution of acriflavine in castor oil 1 : 1500 instilled afterwards. If treatment can be instituted before the cornea is ulcerated, it is possible to avoid this complication altogether. When the patient is at home a daily application of silver nitrate 2 per cent. should be made. Secretion should be frequently wiped away from the lid margins with swabs soaked in pot. hyd. perchlor. 1 : 8000, and the conjunctival sacs washed out from an undine with a similar lotion. A skilled nurse will be able to evert the lids for this purpose, and an effort should be made to have this done every two hours while the discharge is profuse. A daily inspection of the cornea must be made in case any ulcers should form. It is well on first seeing the case to use lid retractors for this purpose, for undue pressure on the eyeball may cause perforation of a deep ulcer. In adults the course of the disease is more severe than in infants. If only one eye is involved, every effort should be made to save the other by keeping the patient in bed—in a well-ventilated room—making him lie on the affected side, and by covering the second eye with a Buller's shield. A daily prophylactic instillation of some organic silver preparation in the unaffected eye is advisable. The diet should be liberal and the patient's general health considered. In the first stage the pain may be relieved by leeches to the temple, the application of cold compresses, and the frequent use of a cold boric lotion. Sedatives, opium, aspirin, &c., should not be withheld. If the lids are very tense the external canthus should be freely divided with scissors. When the stage of suppuration occurs, treatment with silver nitrate and frequent bathing with warm boric lotion are indicated. The attendants should wear gloves and goggles when carrying out the treatment.

Phlyctenular Conjunctivitis.

Phlyctenular conjunctivitis occurs almost exclusively among hospital patients whose general health and surroundings are poor. Should the disease extend far on to the cornea, it may entail serious consequences. The treatment must be constitutional as well as local. The best thing is to get the child into the country and order a tonic such as sy. ferri phos., good and regular food, forbidding sweets in any form. The tonsils and adenoids frequently require removal. Local treatment consists in bathing the eyes with boric lotion, followed by the application of hyd. ox. flav. gr. iii., liq. calcis ♏ x., vaseline flav. ad ℥i., or some other form of yellow oxide ointment, three times daily. It is again important to correct any error of refraction.

Trachoma.

Trachoma may commence as an acute catarrhal conjunctivitis; more usually, however, the onset is insidious. When the granulations are numerous the eye is thoroughly cocainised, or the patient given a general anæsthetic, the everted tarsus gripped between the blades of suitable expression forceps—e.g., Grady's, Tyrrell's, &c.—and the contents of the follicles forcibly expressed. The forceps should be pushed as far into the fornices as possible. After expression the everted lids are brushed with a solution of perchloride of mercury in glycerine (1 : 100) and the sacs are then washed out with boric lotion, boric vaseline being put between the lids. When the follicles are on the tarsal conjunctiva they are often too hard to be expressed with forceps. They may then either be touched with carbon-dioxide snow for 20 seconds (taking care that the frozen area thaws before it is allowed to come into contact with the cornea), or they may be scarified with a Beer's knife, the contents being scraped out with a small Meibomian curette.

There is usually much reaction after these procedures, and iced compresses will be required, also frequent bathing with cold lotion. The subsequent treatment is the same as in milder cases—namely, daily application of copper sulphate stick to the conjunctiva of the lids and fornices. This should be kept up for six weeks or so, when the frequency may be diminished to twice a week, and later even to once a week. It is frequently advisable to change from copper sulphate to 2 per cent. silver nitrate, and occasionally to drop all caustic treatment for a week or two, using only a mild astringent lotion such as boric acid and zinc sulphate. The disease is of long duration, and the average time for cure at the M.A.B. trachoma school, Swanley, Kent, where treatment is carried out under the most favourable circumstances, is 18 months.

F. A. Williamson-Noble, M.B., F.R.C.S. (with Ophthalmology),
Assistant Surgeon, Royal Westminster Ophthalmic Hospital.

Special Articles.

THE VIRUS OF FOOT-AND-MOUTH DISEASE.

(FROM OUR DUTCH CORRESPONDENT.)

IN view of the great importance of the isolation of the virus of foot-and-mouth disease by Prof. Paul Frosch and Prof. H. Dahmen, which was announced in THE LANCET of May 10th, 1924, the Dutch Government invited these workers to give a lecture and demonstration of their discoveries at Utrecht on June 16th. The Minister of Home Affairs, Mr. C. H. Ruys de Beerenbruck, in an introductory address, pointed out that foot-and-mouth disease had become an economic disaster in many countries. Now that the virus had been isolated the outlook was more hopeful, although no practical result could be expected as yet.

PROF. PAUL FROSCH (RIGHT) AND PROF. H. DAHMEN.

The Method of Ultra-Microphotography.

Prof. Frosch began his demonstration by pointing out that it had long been realised that the causative agent of foot-and-mouth disease must be very small, ultra-visible and filtrable. But not a single researcher succeeded in cultivating that germ or in making it visible. The basis for his own attempts to cultivate and photograph the virus was formed by his researches into the morphology of the agent of contagious bovine pleuro-pneumonia (infectiöse Lungenseuche der Rinder). This germ was also invisible, although it had long been possible to cultivate it both on solid and liquid media; Prof. Frosch, in this connexion, called to mind the work of Metchnikoff, Nocard, and Dujardin-Beaumetz. It was necessary to make use of the ultra-microscope and ultra-microphotography. Dark-ground illumination yielded no results. Hitherto ultra-microphotography had been not a means of research, but only a method of registration. Prof. Frosch made use of an ultra-microscope, constructed by Köhler at Jena. Instead of ordinary light with a wave-length of $0{\cdot}550\mu$, he first used blue light ($\lambda = \pm 0{\cdot}40\mu$), and finally ultra-violet light ($\lambda = 0{\cdot}275\mu$). In this way the power of the lenses used became twice as strong. This ultra-violet light was obtained by burning cadmium in the spark of an electric high-tension current. The light which then radiates is intercepted by a quartz prism; the spectrum thus formed consists of a narrow yellow and green-blue zone, and a very wide ultra-violet invisible zone. These ultra-violet rays are intercepted by a lens of quartz glass and conducted to the ultra-microscope, all lenses of which are also made of quartz glass; to it a photo-apparatus is fixed.

Ultra-violet light cannot be seen, still less can it be focused clearly. Work had to be done practically in the dark; this was a great difficulty which could only be conquered after examination of long series of the same object with different focusing. Prof. Frosch showed on the screen a great number of micro-photographs of different trial objects, studied by him in order to master the technique. Thus the ultra-microphotographs of unstained white blood corpuscles showed the nuclear structure far more clearly than does a stained preparation under the ordinary microscope; some white blood cells also showed distinct granulations. He then demonstrated many series of ultra-microphotographs of the causative agent of contagious bovine pleuro-pneumonia. At first Frosch did not succeed in photographing this micro-organism. He therefore concluded that either the agent was too small or it was present in too low a concentration. All attempts to increase the concentration ("Anreicherung") were unsuccessful until he hit on the idea of photographing those cultures only which were grown on solid media. Many difficulties connected with experiments on liquid media then disappeared. Once he had got hold of this idea he managed to obtain fairly good results with blue light and a relative degree of magnification, and he easily contrived to make the organism clearly visible by means of ultra-microphotography. The agent of contagious bovine pleuro-pneumonia was then seen to be not a bacterium but a hyphomycete (*Sprosspilz*): it does not propagate by means of division but by budding, like yeast. Therefore it was called *Micromyces peri-pneumoniæ bovis contagiosa*. Prof. Frosch also succeeded in finding the virus in the smear-preparations from lungs of animals which had suffered from this disease. Thus the way for the ultra-microphotographical research of the micro-organism causing foot-and-mouth disease had been prepared.

Methods of Cultivation.

At this point Prof. Frosch paused in his demonstration in order to enable Prof. Dahmen to explain his methods of cultivation, for it was only after Prof. Dahmen had succeeded in cultivating the virus of foot-and-mouth disease on a solid medium that Prof. Frosch was able to photograph it.

Prof. Dahmen then gave a summary of the experiments to obtain cultures of this filtrable virus made before and after the war. Until now none of them could be called successful. The last attempts were those made by Prof. W. Pfeiler, who, however, did not publish his method of cultivation nor the composition of his media; for this reason it had not been possible either to confirm or to dispute his claims. Prof. Dahmen himself had tried a great number of media. In some cases turbidity had resulted; this had been noticed also by Pfeiler[1] and Titze,[2] and looked upon by them as caused by the virus. The turbidity proved, however, here, as in contagious bovine pleuro-pneumonia, to be the result of a precipitation of albumin. This became apparent when it became possible to isolate the agent; the fluid remained turbid but was not infectious. Prof. Dahmen then examined the fluid from the aphthæ of animals suffering from foot-and-mouth disease. He came to the conclusion that the virus soon died in that fluid, and that its death was hastened when the temperature at which the liquid was kept was allowed to approach that of the animal body. From this observation he drew the conclusion that the fluid in the blisters was not, as Titze, among others, had asserted, an ideal medium for the foot-and-mouth disease virus, but, on the contrary, a reaction product of the body which serves to make the agent innocuous. At first he thought that he had to deal with the d'Herelle phenomenon, and although no trace of the presence of a bacteriophage was found, yet this hypothesis had a great influence on his further researches. The task was now to separate the virus from the blister fluid or at least from the noxious substances contained therein. After many fruitless attempts to achieve this by means of animal carbon, starch, red blood cells, &c., he eventually succeeded in effecting the isolation by diluting the blister liquid with physiological salt solution, and by centrifuging it very quickly for one-half to two hours (up to 3000 revolutions per minute). At the bottom of the test-tube a residue was formed; the upper part of the liquid which remained turbid could be separated by means of a capillary pipette. The residue remained infectious whereas the supernatant fluid had lost its infectious properties. This was the first step on the road to success. The second step was the success of the cultivation tests on solid media. After having tried many of these the best results were obtained with Martin broth, with 3 per cent. agar, 2 c.cm.; horse serum or some other animal serum, 2 c.cm. The mixture was made liquid by means of heating it at 50–55° Celsius, and was put into a test-tube and left to solidify in a slanting position. The infectious material was smeared on this medium. Only after six days was there visible a very fine substance, which appeared to consist of numerous colonies of the size of a red blood cell (7–8μ). Once it had been cultivated on this solid medium it was easy to continue cultivating the virus on various liquid media if desired.

[2] Berliner Tieraerzliche Wochenschrift, 1922, 37.

After having succeeded in cultivating the agent on solid and liquid media under similar growing conditions, the observers were able to infect experimental animals with the fifth, thirteenth, and twenty-third subcultures. In all these experiments they followed the method of Waldmann and Pape,[3] which consisted in rubbing the infective material onto the back of the metatarsi of guinea-pigs with skin scarification. The primary blister (aphthæ) symptoms then appeared after 24 hours. The secondary symptoms (secondary blisters and salivation) appeared after three to four days. In most cultures the virulence appeared to diminish, but could again be brought up to a high level by means of passage through an animal. Some strains, however, retained their virulence. Infection tests on cows were equally successful. Prof. J. Waldmann, on the Isle of Riems, had enabled Dahmen to experiment on the fluid from the blisters of pigs. In consequence of this there were now available six guinea-pig strains, two cow strains, and two pig strains, which were regularly cultivated and of which the twenty-sixth subculture had already been obtained. The guinea-pigs artificially infected with this disease proved to be immune against a generalised infection after the symptoms had disappeared. Immunising tests on cows had also been made on a modest scale. Naturally veterinarians and farmers were greatly interested in these tests. All that could be said at present was that the preliminary results were favourable; the time was too short to enable any conclusive results to be obtained.

The Virus Photographed.

At this stage Prof. Frosch resumed his demonstration and discussed the ultra-microphotography of the virus of foot-and-mouth disease, which was a far more difficult problem than that of the virus previously photographed. The attempt had only become possible after Prof. Dahmen had succeeded in cultivating the agent on a solid medium. Macroscopically, after five to six days' cultivation it was hardly possible to see the fine substance, but microscopically numerous small colonies, the size of a red blood-cell (7–8μ), were visible. More was seen as the magnification was increased and the wave-length of the light used decreased. It was, however, always necessary to take many photographs, because of the impossibility to focus sharply. It finally appeared that this virus was neither a hyphomycete nor a protozoön, but a real bacterium. Its manner of growth on the solid medium had already made this seem probable. The virus proved to be a short bacillus. Direct measurement was impossible, but the length had been estimated at 0·1μ. More detailed calculations were being made.

Both speakers had communicated their discoveries at meetings of the Berliner Microbiologische Gesel-schaft of April 7th and May 19th,[4] and had proposed to call the new bacillus the *Loeffleria Nevermanni*.

Confirmation.

The German Department of Agriculture, with whose help this research was made, had now given consent to the complete publication of all particulars and technical details. At the request of both researchers, a committee of six was formed to examine their discoveries. This committee consists of Prof. H. Titze and Prof. F. Giese of the Reichsgesundheitsamt, Prof. H. Kleine and Dr. H. A. Gins of the Institute Robert Koch, and Dr. Lührs and Dr. Richter of the Heeres Veterinär: Untersuchungsamt. This committee was supplied with material of the sixth and twenty-sixth subculture, and Prof. Kleine had been able to state on May 19th that the infection tests with this material gave positive results.

Discussion.

Prof. Dr. H. Remmelts, director of the Dutch Veterinary Service, who was in the chair, thanked the Minister of Home Affairs and Agriculture, on the part of the meeting, for his presence, and Profs. Frosch and Dahmen for coming to Holland, and congratulated them on their researches. Dr. D. A. de Jong, professor of comparative pathology at the University of Leiden, asked whether Profs. Frosch and Dahmen intended to continue to work on the valuable discoveries—on which he congratulated them—since no definite results with regard to the struggle against foot-and-mouth disease, appeared to have been obtained. Dr. L. de Blieck, professor of parasitology, infectious diseases, and bacteriology at the Utrecht Veterinary College, asked Profs. Frosch and Dahmen their opinion of the cultivation method of Pfeiler, and of the results obtained by the latter, and also of the cell-inclusions (Zelleinschlüsse) described by Dr. Gins.

Reply.

Prof. Dahmen, in reply, said that he could not and would not take upon himself the responsibility of positively answering the question whether immunisation was now more possible than it had been hitherto. Many experiments during a long period of time would be needed to solve this problem. As far as the experiments of Pfeiler were concerned, Prof. Dahmen informed the meeting that Pfeiler now claimed the priority of the discovery of the foot-and-mouth disease virus. Prof. Dahmen did not want to claim this priority for himself in case Pfeiler should really prove to have cultivated the causative organism. The claim could only be examined when Pfeiler published his method and the composition of his medium, which he had hitherto refused to do.

Prof. Frosch, in reply, said that the value of their discovery should be neither over- nor under-rated. As for the cell-inclusions of Gins, Gins has never pretended that these were the agents of foot-and-mouth disease. With Prof. Pfeiler's collaboration his claims could be investigated, even without publication of his method of culture or the composition of his medium, if he would allow his cultures to be inoculated on to the media of Frosch and Dahmen; if the cultures grew, then his claim for priority could be established.

Prof. Dr. Remmelts, in thanking the speakers, pointed out that while the practical application of the discovery was still uncertain, the prospects which the discoveries of Frosch and Dahmen had opened out in microbiological research were anyhow of outstanding value.

BRITISH HOSPITALS ASSOCIATION:

ANNUAL CONFERENCE.

THE fourteenth annual Conference of the British Hospitals Association was held on June 12th and 13th at Victory House, Leicester-square, Sir Arthur Stanley, the President of the Association, being in the chair. Some 260 delegates from all parts of the United Kingdom were present.

On the opening day the delegates were formally welcomed to London for the Conference by Sir Humphry Rolleston. In the course of his address, Sir Humphry Rolleston said that the voluntary hospital system was characteristic of the British temperament. Individual effort had done incalculable work in raising the standard of clinical medicine to its recognised high position. Formerly the voluntary hospitals had acted individually, but that Association had brought them into close contact and enabled them to work as a whole. Instead of no policy or individual and varying policies, it should now be possible by means of those Conferences to have a united and strong policy on the various knotty problems arising between the staffs of the voluntary hospitals and the hospitals themselves, in connexion with the receipt by the hospitals of direct contributions for benefits conferred.

Dr. F. N. Kay Menzies read a paper on the

Future Relations of the Voluntary Hospitals to the Municipal Authorities.

Having passed in review the remarkable developments which have taken place during the last 15 years in the relations between voluntary hospitals and public health and education authorities, he pointed out that in London alone at least four-fifths of the treatment available for the sick was provided for out of rates and taxes. Those services were likely to expand in the near future in certain directions which hitherto had either not come within the scope, or only slightly so, of local authorities, such as municipal maternity hospitals, treatment of certain diseases of childhood—for example, chorea, rheumatism, infantile paralysis, &c., and advanced cases of tuberculosis. Further developments in the Poor-law medical service might prove to be a big factor in determining the ultimate relationship of the voluntary hospitals and the municipal authorities. Probably the future development of the Poor-law infirmary was in the direction of a municipal hospital. Were those infirmaries to become merely competitors with the voluntary hospitals, or were they to work in coöperation with them? He believed that every right-thinking man and woman in the country was beginning to realise that the present position with regard to the prevention and treatment of disease, whether by voluntary or public authorities, required review. The time had, in fact, come to make a careful, comprehensive, and detailed survey and study of the situation. He could not see any reason why such a scheme when drafted should not provide: (1) for the preservation of the best features of the present voluntary hospital system; (2) for adequate accommodation, equipment, and finance of the hospitals generally; (3) for the geographical distribution of hospitals so as to avoid unevenness and overlapping; (4) for a closer relationship between voluntary hospitals themselves, between voluntary hospitals and the various classes of hospitals provided by local authorities, and between general practitioners and all the various institutions which treat the sick.

Lord Hambleden, in opening the discussion, said that Dr. Menzies's paper had been both interesting and suggestive. He agreed with Dr. Menzies that the voluntary hospitals would have to face the question of their future relations to the municipal authorities within a comparatively short time. He (Lord Hambleden) did not know whether a further development of the health insurance scheme would lead to a larger demand for institutional treatment. If it did it would, of course, lead to the necessity of a very large increase in the hospital beds throughout the country. One important point to be considered was whether, supposing grants were made either by the local authority or the central government to the hospitals, they were likely seriously to affect the voluntary subscriptions. Personally, he doubted whether such grants, if given, would be likely to affect the teaching hospitals in the same way as they might hospitals which had no medical school attached to them. It was important that they should get to know what was likely to be required of the voluntary system in the future in regard to hospital accommodation, and how best that system could take a part in any scheme which might be devised; but it would be a very great mistake to suggest that they would not work in with any general policy which the Government and the country might decide to pursue.

Lord Armstrong set out the experience of Newcastle-upon-Tyne, where the people gave very liberally to the Royal Infirmary. There was, he said, a great prejudice on the part of patients against going into the Poor-law hospitals, and he was afraid that prejudice was pretty general in the north of England. The corporation of the city were giving his hospital £500 a year for looking after the street accidents, but that was as far as they could assist them under their present powers. On the other hand, the Manchester Infirmary got £8000 a year from the city. What was wanted was a short Act of Parliament removing the restriction imposed by law against local authorities subscribing to hospitals.

Mr. H. M. Crouch (Bath) moved, and Dr. C. E. S. Flemming (Bradford-on-Avon) seconded, the following resolution, which was passed: "That the time has come to make a careful, comprehensive, and detailed survey and study of the hospital situation in the country, and to formulate an adequate and coördinated scheme for the prevention and treatment of disease throughout the whole country; and that the Council of the Association be instructed to consider how the survey can best be made, and to give all the assistance in its power to any body that makes it."

In the afternoon Sir Wilmot Herringham spoke on the

Training of Nurses.

He recalled that the first serious training school of nursing in England was set up at St. Thomas's Hospital in 1860, in commemoration of Miss Nightingale's work in the Crimean War. In 1877, when the speaker went to St. Bartholomew's Hospital as a medical student, the first regulations for the training of nurses were introduced. The period of training was one year, the age of admission was 20, and two inspectors were employed—one from the medical, one from the surgical side. In 1882 the period was extended to three years, and the age of admission was raised to 23, an examination now being instituted at the end of the first year, and another when the course was completed. In 1914 the admission age was lowered to 22, in 1918 to 21, and in the following year a committee reported on the nursing curriculum, with the result of producing the present nursing curriculum of the General Nursing Council. He well remembered the old type of sister, a very capable and practical person; very often kind and compassionate, but quite unfitted to do the work required of the modern nurse. In one respect, however, modern nursing was rather at a disadvantage in comparison with the former time. Formerly many educated women took up nursing, largely because that was practically the only means for them to earn a living. As there were now many business and professional openings, it was not surprising that fewer of these women entered the nursing profession, and nursing was the poorer for their absence. The General Nursing Council had to determine what policy ought to be adopted in regard to the training of nurses. The syllabus which the Council drew up was, in essence, that which had been obtaining for three or four years at the best training schools. When the Minister was asked to sanction this syllabus, as a result of Parliamentary pressure he declined to do so. That turned out to be a fortunate circumstance, because if the Minister had sanctioned the scheme it would have become law, and not only would it have become compulsory on the schools, but, like all legal things, it would have been unchangeable, and the last thing those who formulated the scheme wished was to stereotype the method of education provided. In both cases when the syllabus was submitted to an outside body—in one case a general meeting of nurses and in the other the Ministry of Health—it was the outside body which demanded additions, not the Nursing Council. Some might object that the syllabus embraced too much theoretical knowledge, that it was unnecessary to teach the nurse anatomy, physiology, pathology, and bacteriology. It was true that Miss Nightingale's "Notes on Nursing" was one of the best books ever written on nursing, and contained very little pathology and no bacteriology. It consisted in injunctions to nurses to be kind and sympathetic, not despotic or tyrannical; incidentally, of all the despotic ladies who ever made men shake in their shoes, Miss Nightingale was the most relentless. Though she laid down a standard of excellence which no period could excel, Sir Wilmot Herringham combated the idea that the modern nurse should have no theoretical training; she should know of the ubiquity of micro-organisms and of their virulence, and this aspect of medicine could not possibly be omitted from her course of training.

In the course of the discussion on Sir Wilmot Herringham's address, Dr. H. L. Eason referred to the affiliation of the larger hospitals with some of the smaller ones for the purpose of giving their nurses a wider experience. For example, Guy's Hospital was being affiliated for this purpose with the Royal Sea Bathing Hospital of Margate, with the Cancer Hospital, and with the Evelina Hospital for Children. Dr. Eason discussed also the report on Nursing and Nursing Education in the United States,[1] published by the Rockefeller Foundation. The schedule outlined in this report was far too extensive for the proposed two years' course. American visitors were very critical of the training of nurses in British hospitals, but they all agreed that the English nurse produced by our system was a type they could not beat.

Sir Wilmot Herringham, in reply, said that he entirely shared Dr. Eason's view of the Rockefeller report. Nursing was an art which had to be learned by patience and by practice, and could not be taught by intensive methods. In answer to other questions as to the recognition of certain hospitals as training centres for nurses, he explained that where the interests of the hospitals clashed with the interests of the public they were bound to consider the public. That was the whole gist of the case for the General Nursing Council. Every case that came up was treated on its merits.

The following resolution, proposed by Mr. John Barker (Grimsby), and seconded by Mr. Watts (Great Yarmouth), was carried: "This Conference requests the committee of the British Hospitals Association to consider the ruling of the General Nursing Council as to the number of medical beds and also medical cases at present required to obtain their certificate, and if there should not be an amendment of the rules so that smaller hospitals which do important surgical and medical work and afford adequate training can be duly approved."

At the Friday morning session, Sir Arthur Stanley again occupying the chair, a paper was read by Mr. R. J. Meller, M.P., on

Approved Societies in Relation to Voluntary Hospitals.

Mr. Meller said the relationship existing at present between that Association and the approved societies was a cordial one. There was a close affinity between their work, because the main work of the approved societies was not to pay cash benefits, but to see that every assistance was rendered to the sick and suffering. The approved societies regarded the convalescent home aspect of hospital work as of the utmost importance. The scheme of health insurance provided for only such treatment as could be given by the practitioner selected by the insured person. The hospitals not only trained the practitioners, but also enabled them to keep in touch with medical advances. The hospital stood in the same relation to the insured population as did a nursing home to people more fortunately placed, and there was now no hesitancy on the part of the mass of the people to enter a hospital. The Cave Report in 1921 stated that in the Metropolitan Police District there were 117 hospitals, in the rest of England and Wales 728, in Scotland 107, totalling 952. The number of beds available were: London 12,797, England and Wales 31,265, Scotland 8132, just over 52,000 in all. There were 15,000,000 insured people to be catered for, apart from women and children. If the contributions from approved societies could increase the number of beds available, or reduce the deficiency, there was ample justification for the support now being given. In the Cave Report it was stated: "While we hold that the approved societies are not under any obligation legally or equitably to provide the whole cost of the maintenance and treatment of their members in hospital, we are strongly of opinion that they do owe to the hospitals a large measure of support." That view, Mr. Meller said, he accepted. The group of societies with which he was connected was able, during the year 1923, to distribute £170,000 to the voluntary hospitals, and he anticipated a similar sum would be available for the present year.

Mr. G. Q. Roberts (St. Thomas's Hospital) spoke warmly of the zeal in the cause of the hospitals which had been displayed by Mr. Meller at the numerous conferences and meetings he attended. Mr. Roberts thought much more should be done by the approved societies in helping the hospitals, and it was necessary to disabuse workers of the belief that the contribution made to their hospital treatment was a defraying of the cost, especially in the cases of serious illnesses. The payments made were not insurances carrying the right of entry of the payee into a hospital. There were still many societies which did not make a hospital grant. There was a growing number of persons coming forward for hospital treatment in respect of whom no payment was received, and that was an anomaly which must be tackled. The preventive work being done in the voluntary hospitals was of increasing importance: responsible men were in charge of out-patients, for whom all the agencies of the hospital and its apparatus were enlisted.

Mr. S. R. Lamb (Sheffield) said it was found difficult to convince business men, particularly in the provinces, that in contributing to hospitals they were not paying twice over for the medical benefit received by the worker. The Prudential group had shown themselves very willing to provide convalescent service. It was said that if a patient seeking hospital treatment was not a panel patient, he must be turned away, but that would be found very difficult in practice. Many approved societies had not yet been made to understand what were their responsibilities to the hospitals. The voluntary hospital accommodation in this country for insured persons cost 7¾ million pounds per annum, and a reserve fund was being set aside of 7 millions a year.—Mr. E. C. Lindsay (Poplar Hospital) said the Friendly Societies used the Poplar Hospital more than did any other class or section of the community, and its application for help had been turned down. He asked that the executive would take the case of that hospital into consideration.—Lord Hambleden expressed his gratitude for the way in which the approved societies had acted; in consequence of that action the position of the voluntary hospitals was now much stronger than four or five years ago. It was hoped that at the next valuation the societies would be able to increase their grant, and this hope was increased by the general agreement that the voluntary system was the best for the hospitals.

---

[1] See The Lancet, 1923, ii., 1203.

Mr. Meller replied that he had long realised that something additional was required to the benefits provided under the panel system. To those who thought something should have been done by the approved societies under Section 21, he would reply that in the first few years of the Insurance Act the matter was in an experimental stage, as all lives, not selected lives, had to come into the consideration. He thought it would be seen that the greatest advantage was to be secured not by giving additional cash payments, but by giving such benefits as would best conserve and improve the health of members of the societies. Not every insured person was entitled to additional benefits. Again, it must not be assumed that large reserves meant enormous profits which would never be distributed; but he could say that the improved condition of matters would probably result in the societies becoming liberal instead of conservative. A Royal Commission was to be appointed to go into the whole question of National Health Insurance, to consider its defects and its values, and to recommend, if necessary, extensions and improvements, and he urged that this Association should seek to give evidence before that Commission.

British Hospitals Association Dinner.

Lord Hambleden presided at the dinner held at the Royal Automobile Club, London, on June 19th, in connexion with the annual conference of this Association. There was a large attendance. The dinner was good, the speeches short and witty, and the guests went home at a reasonable hour well satisfied that the function had further cemented the bonds between all those interested in the hospital problem. The toast of the Association was allocated to Lord Stuart of Wortley, who praised not only the efficiency of British hospitals, but their independence of spirit. This very independence, however, made it difficult for them to find a medium of common expression and, when necessary, a means of common defence. The British Hospitals Association would presently subserve these functions; no attempt at unification would be made, but at least the first step towards collective action would be provided. The voluntary hospital system had been challenged; many of the ideals set out by those who challenged it were shared by its supporters and were undisputed, but some of them at least were not at present compatible with the national resources.

Sir Arthur Stanley, responding to the toast, referred to the superannuation scheme for nurses which would soon be adopted by all hospitals. Lord Hambleden, toasting the guests, noted that this was the first regular conference to be held in London, and expressed appreciation of the interest shown by distinguished bodies and persons in their deliberations. Sir Humphry Rolleston replied, referring gratefully, on behalf of the medical staffs of hospitals, to the efforts made by the administrative officers to cope with the many difficulties now besetting these institutions. Sir Wilmot Herringham, who also replied for the guests, said that as chairman of the General Nursing Council he appreciated the cordial coöperation of the hospitals throughout the country in the attempt to improve the training of nurses. Lord Knutsford, who proposed the health of the chairman, and Lord Hambleden, who replied, alluded merrily to the claims for support of the great institutions with which each was specially connected, and in this friendly rivalry the guests found much amusement.

VOLUNTARY HOSPITALS COMMISSION.

THE Conference of the Voluntary Hospitals Commission with the Local Voluntary Hospitals Committees was held on June 18th at the Ministry of Health, Lord Onslow, chairman of the Commission, presiding. In THE LANCET of last week we gave a brief résumé of the morning's proceedings, the principal points brought forward by representatives of the Local Voluntary Hospitals Committees in reply to the inquiry into the extent of voluntary hospital accommodation in England and Wales, and the best means of providing and maintaining it. Towards the close of the discussion, Lord Cave said he was glad to think the system of mass contribution, the contribution from workers and employers, had grown and prospered. He thought that the amount collected in that way annually would be a very considerable one. He referred to Sir Walter Kinnear's report dealing with contributions from the approved societies (which was read at the meeting by Lord Onslow), and said that this system, which now brought some £200,000 annually to the hospitals, had become a vital part of the whole organisation. A great Friendly Society had set the example in this respect, an example which had been widely followed. Referring to the need of further beds, the speaker thought that the need existed more in the case of the larger hospitals which served a large surrounding area than in the case of the small cottage hospitals which were strongly supported locally. While the inquiries are being made into the needs of each county, he thought the committees ought to take a wider view and consider not only what the hospitals wanted in the way of further beds, but what the country wanted in the way of further hospital accommodation, which at present was not sufficient. In concluding, he expressed his feeling that even if these committees were to be dissolved forthwith they had done admirable work throughout the country, but he hoped that for years to come they would continue to render useful services.

The Chairman, in summing up the discussion, considered that all the points raised would furnish most useful information for the further inquiry which the Commission was going to undertake. It was very important to remember, he said, that the hospital needs of various areas differed very widely.

At the afternoon session a discussion took place on the

Future Functions of the Local Voluntary Hospitals Committees,

which was raised by the Worcestershire and Somerset Committees. Mr. Crouch, of the Somerset Committee, said that he wished to put forward the idea that the Voluntary Hospitals Committees should regard themselves as guardians of the public in regard to hospitals generally, and he understood that the Minister of Health approved of that idea. We should not, he said, seek to criticise or interfere with existing hospitals, but we should make it our business to see what the country wanted in respect of hospital accommodation and in respect of hospital treatment, and take such steps as are reasonably within our province in order to get that hospital service provided. The Commission should formulate a policy and a detailed programme. The speaker then gave some comparison between the existing hospital position and the ideal one. Early hospital treatment would save a great deal of suffering. The whole country wanted hospital treatment, middle-class people as well as the poor, but at present it was nobody's business to get it for them. From experience in Somerset, in his opinion, in order to discover what additional accommodation was needed, it was necessary to know not what the hospitals were doing, but what they were not doing. In conclusion, Mr. Crouch said that it appeared the committees were expected to try and effect some coördination between the voluntary hospitals and the municipal and county health officers and with county institutions. Nothing could be done in that direction unless the areas to be dealt with were suitable for that work. He and his committee, therefore, put forward a resolution: "That the country be divided into effective hospital areas, and that each committee include the medical officers of health and adequate representation of the local doctors."

The Chairman said that he did not think this would be an easy matter to carry out, owing to local difficulties. He was of the opinion that the coördination of Local Voluntary Hospital Committees in the local areas must be left entirely to the hospital committees, the county committees themselves. The county committees knew their own local requirements much better than the Commission did, and he quoted a case in point from Yorkshire as an illustration.

Mr. Davis (Manchester) said that there was a lack of coördination among Voluntary Hospitals Committees, and as a result the hospitals and the community did not get the full benefits they might have expected from the committees. A centralising authority was required to bring about coördination, an authority through which the local committee might approach the Government. There was a feeling in certain important quarters, he said, that it would become necessary for the Government to subsidise the voluntary hospitals without taking over control and administration. If this came about, the need for a centralised committee would be ten times greater. The chairman then suggested that the points raised by Messrs. Crouch, Davis, and others should be brought before the local voluntary committees, and when they had been fully considered a further Conference might be held to put forward further ideas and further methods of procedure in the way of carrying on the functions of the local hospital committees. This was agreed.

Mr. Lamb (Sheffield) then dealt with the question relating to the

Contributions to Hospitals by Municipal Authorities and Insurance Organisations.

He said that business men who were asked to subscribe to the work of the hospitals were asking questions as to why it was the hospitals did not get the insurance companies to make much more generous contributions for the maintenance of the patients who, for instance, were run down by motor vehicles in the streets, and that if the patients were to go to a nursing home he believed the insurance company would pay up like lambs. He hoped that through the British Hospitals Association or the Commission a Conference might take place with those representing the largest and wealthiest insurance companies in order that a larger measure of conscience might be secured from them as to what they should do for the work of the hospitals. "We would much prefer," he said, "that they should pay something voluntarily, as an act of grace." He also suggested that the Commission might help by recommending to the Ministry of Health that local authorities be empowered to contribute, if only in their capacity of employers of labour. Referring to the surplus funds of the National Health Insurance, he said that at the last quinquennial period there was a surplus of about 15 millions, of which 7 millions was divisible, and of that sum the voluntary hospitals had not received more than half a million. Mr. Lamb then proposed: "That in view of the forthcoming quinquennial valuation under the National Health Insurance Act, the Minister be asked to receive a deputation seeking his advice as to approaching the approved societies throughout the country."

The resolution was seconded, and on the Chairman's suggestion that the proposer and seconder should consult with the Minister of Health or Sir Walter Kinnear on the matter, this was agreed.

A vote of thanks to the Chairman having been carried unanimously, the Conference then adjourned.

ROYAL INSTITUTE OF PUBLIC HEALTH.

FURTHER NOTES ON THE CONGRESS AT BORDEAUX.

The Annual Congress of the Royal Institute of Public Health was held at Bordeaux from June 4th–9th, Viscount Burnham presiding. On the evening before the Congress Sir Humphry Rolleston delivered a lecture on endocrine therapy, and both he and Sir John Bland-Sutton were awarded the honorary degree of Doctor of Medicine of Bordeaux.

Lord Burnham opened the Congress on June 9th, when the gold medal of l'Assistance Publique was awarded to him, to Sir Thomas Oliver, and to Sir W. R. Smith; the rosette d'Officier de l'Instruction Publique to Lady Bland-Sutton, Lady Smith, and Dr. Kelynack; and the bronze medal of the Bordeaux Municipality to Mrs. Werner Göthe.

Antityphoid Inoculation.—In the course of a lecture Prof. C. Achard (Paris), dealing with antityphoid inoculation of the civil population, reminded the audience of the compulsory vaccination in France of members of hospital staffs who were likely to be infected by typhoid or paratyphoid fever in the course of their duties. In 1912 and 1913 many of the inhabitants of 24 villages had been inoculated against typhoid fever with marked success. He did not recommend compulsory vaccination against typhoid of the whole of the civil population. In the course of discussion Dr. C. W. Hutt (Holborn, London) said that Prof. Achard's paper had dealt another severe blow to the theory that it was dangerous to attempt artificial immunisation of a population in the presence of an epidemic. The absence of danger was also borne out by the results of the preventive antidysenteric inoculation carried out in Egypt during the war. Prof. Hope (Liverpool) believed in vaccinating armies and persons who were about to proceed to districts where the danger of typhoid was great, but not in vaccinating the civil population generally. Success had been attained in England without recourse to this measure.

Tuberculosis.—Several papers dealt with tuberculosis, including one by Prof. Léon Bernard (Paris) on pregnancy and tuberculosis. The discussion, in which Prof. Besançon took part, revealed a partial belief among the French in the value of preventive measures such as the use of masks by tuberculous mothers when suckling and the careful washing of the nipple, but the firmest belief was placed in separation of the infant from its mother. The value of *pouponnières et centres d'élevage* was stressed by Prof. Mouisset, who also pleaded for the provision of a preventorium attached to each dispensary for children from 5 to 13 years of age, and Dr. Bushnell (Plymouth) agreed that these would be useful.

Dr. Pierret (La Bourboule) praised the efficacy of the arsenical water of his town as a means of combating tuberculosis, and Prof. Leuret (Bordeaux) urged the need of teaching consumptives a craft while still in sanatoriums. The chief point made by Prof. Courmont (Lyons) was that the dispensaries of the Calmette type were playing a large part in the diminution of tuberculosis in Lyons. Arrangements existed at the central wash-house in this town for the disinfection and washing of the linen of all cases of open tuberculosis.

Propaganda.—Dr. René Sands, Secretary-General League of Red Cross Societies, spoke of the three-fold duty fulfilled by the Red Cross—education, coördination, and experimentation. These functions were discussed by the delegates. Lord Burnham regretted that in spite of the existence of important international organisations there was not adequate coördination of international health activities.

During the discussion of the paper on propaganda of Dr. Daley (Blackburn), Sir Humphry Rolleston referred to the need for a balanced programme in connexion with health instruction; he did not approve of lectures confined to one topic such as tuberculosis or venereal disease. It was evident that in the north of England the labouring classes would attend such lectures in large numbers, especially if they were shown a film. Dr. Annis (Greenwich) said that he would like to learn the best way of advertising these lectures because the cost per head of those who attended often worked out at a relatively very big figure.

The Treatment of Organic Nervous Disease.—From a paper by Dr. J. Roubenovitch (Bicêtre) it emerged that the Conséil Générale of the Seine had initiated as an experiment at the asylum for the department a special hospital for the treatment of patients suffering from organic nervous disease, neurosis, and psychoses who could not be certified as insane on admission. Of 1019 in-patients only 157 had been sent on to the asylum.

Industrial Hygiene.—Dr. C. S. Thompson (Deptford), discussing the health of the clerk, showed that the order of superiority in health was insurance, bank, civil service, railway (all of whom had to pass a medical examination), law clerk, the worst being the commercial clerk. Tuberculosis and neurasthenia were common among law and commercial clerks. The remedies were, in his opinion, more thorough inspection of offices as regards ventilation and lighting, both natural and artificial, trade unionism, and a pension fund. The contribution of Dr. Clark Trotter (Islington, London) indicated the part played by the municipal health department in connexion with industry and industrial welfare. He said that to discover workshops in Islington a watch was kept on advertisements in local newspapers. He complained of the absence of legislation to prevent the almost surreptitious establishment of a factory in residential parts of an area. Factory hygiene was retarded by the present unsatisfactory medical arrangements. In a discussion on the protection of workers from the effects of carbon monoxide, Prof. Rochaix (Lyons) advocated the use of electric stoves for drying materials after the use of various dressings in connexion with dyeing, leather work, and millinery.

Women and the Public Health.—The best attended section was that dealing with women and the public health. Madame Saint Luc gave an account of the training and work of a health visitor (visiteuse), whose duties in France comprise visiting the homes in connexion with maternity and child welfare; the health visitors also carry out minor nursing duties for babies, such as giving enemata; they attend the clinics of the children's hospital, where they administer subcutaneous injections of sulpharsenol or even intramuscular injections of bismuth salts to children and mothers. The course of training for this position lasts for three years. The health visitors are paid by the Fédération des Œuvres, which is subsidised by the city and the department. At Bordeaux six health visitors put in an attendance either weekly or fortnightly at the 30 different institutions carried on by the various œuvres. Assistance at the school medical inspections is afforded by pupil health visitors. A separate set of nurses, all of whom possess a diploma, now visit the homes of tuberculosis patients. They do not work under an Œuvre but are paid direct by the municipality and department. In these smaller towns—e.g., Soissons—the health visitors undertake all branches of health visiting. Each of the V.D. clinics in Bordeaux has a whole-time nurse; in the smaller towns in France these nurses visit the homes to endeavour to get the husband or wife and the children to come up for treatment if necessary. The œuvres appear to be heavily subsidised in France either by the municipalities or the State, and there seems to be a general feeling that these numerous activities should be combined and more directly controlled by the State. Besides the health visitors, there are officials, called *assistantes sociales*, who also visit the homes and do most of the work which the more developed English organisation has grouped in the duties of the female staff of public health departments; they do not carry out minor nursing. These *assistantes sociales* are trained nurses and are paid by the State. Several hospitals in Paris have these officials, the creation of the posts being due chiefly to the efforts of Profs. Calmette, Léon Bernard, and Armand Delille.

In the course of communications on the work of the hospital almoner, made by Miss Cummins (London) and Miss Lyall (Glasgow), it was stated that two years' training arranged by the Institute of Almoners would be extended as soon as possible to three years. The almoner does not visit the homes, visits being paid by the public health staff, district nurses, and Charity Organisation Society visitors, working in coöperation with the almoner. Papers of interest in other sections were one by Mr. Saint Sernin, recommending the use of chloropicrin and Tissot's apparatus for the destruction of insects; this substance can be used without danger of fire; it has no action on metals, furs, fabrics, or colours. Prof. Neveu Lemaire (Lyons) delivered a suggestive paper on the prophylaxis of bilharziasis, discussing the possibility of destroying the molluscs, the hosts of the larval stage of the parasite. Prof. F. Mésnil (Paris) considered that at present this means of prevention was impracticable.

Visits.

Prof. Bergonié, who has lost his right arm as the result of his pioneer work in radiography, showed the delegates over the Centre Régional Contre le Cancer de Bordeaux et du Sud-Ouest. Inoperable cases of cancer are treated by X rays and radium, of which they possess 185 mg.; when the centre was first opened operable cases were treated, but as the results obtained were no better than those achieved by surgical operations the procedure was abandoned. At the Military, Naval, and Air Force Hygiene Exhibition, among the appliances shown was a Clayton's disinfecting apparatus. In a small pavilion the technique used for preventive inoculation against typhoid and paratyphoid fevers, dysentery, and gas gangrene were shown, together with clear diagrams depicting the results achieved. Visits were also paid to day nurseries, the Florence Nightingale School for the training of health visitors, the hygienic institutions at Arcachon, including the Basin, the saline baths at Biarritz, and the sulphurous baths at Luchon.

THE FEDERATION OF MEDICAL AND ALLIED SERVICES.

THE annual dinner of the Federation was held at the Connaught Rooms, Great Queen-street, London, W.C., on June 20th, with Sir Berkeley Moynihan, the President, in the chair. There was a good attendance of members, and among the guests present were Mr. Wheatley (the Minister of Health), Sir William Joynson-Hicks, Sir Arthur Robinson, and Mr. St. Loe Strachey.

Sir Berkeley Moynihan, in proposing the toast of the Prime Minister and of the Minister of Health, said that happily the Federation had no political attachments, and that the annual dinner had always been attended at different times by members of the Government whatever party was in power. He read a letter from the Prime Minister, who was to have been present, but was prevented by the visit of Mr. Herriot. In this Mr. Ramsay MacDonald described national health as "the foremost asset of the nation," and approved the aim of the Federation "to make available for all sections of the community a body of expert scientific opinion ready to lend both to the Government and to the public generally deliberate judgment in all questions affecting health policy."

The Federation, said the chairman, placed in the forefront of its faith the nationalisation of knowledge of the state of the nation's health and of the best means of remedying it. Most members of the medical profession had, he said, been compelled to realise that they could not advance much further without coördination, and that there were some occasions when an alliance with the public in the interest of public health was necessary. During the last general election there was some discussion as to the principles of trading and the best methods of providing raw material, "but so far as I have been able to learn," went on Sir Berkeley Moynihan, "the most important of all raw material was never mentioned in that discussion from beginning to end; for the most important raw material in every industry is the baby. Sir George Newman, in one of those pamphlets which are not only a mine of information but also a model of fine English, has told us that there are in this country 1,000,000 children unfitted to receive the education which the State provides because of disabilities which are preventable, and in the war we learned that there were 1,000,000 men unfit to be placed in any category also because of disabilities which were preventable. It is true that such men can be treated in the hospitals of this country, but the hospitals of the country are unable to accommodate them. The whole question of hospitals in this country is ripe for revision and review. They are our noblest heritage. They have been built, endowed, and equipped by the self-imposed taxation of benefactors in days gone by; but auto-taxation ceases to become a pleasure, and may become a peril if the State takes from you all that you can spare—and then a little more. And I would ask with regard to our hospitals whether there are any hospitals which deal with *all* the people who seek and need their aid, whether there are hospitals which have *all* the adequate equipment that they require, and if any hospitals have an opportunity of carrying out those measures of research, which is some of the most important of the work done within their walls?" Sir Berkeley Moynihan concluded an eloquent address by referring to the high ideals of the Prime Minister and to the practical attainments and strong character of his colleagues. Referring to the guests, he added that among them were men who held a very distinguished place among those who were serving their country.

Mr. Wheatley, on behalf of the Prime Minister and the Government, and particularly on behalf of the Ministry of Health, expressed his pleasure at the healthy state of the Federation. If fully realised, its objects would serve a very useful purpose—namely, that of bringing into a common channel the experiences and medical opinions of people engaged in medical practice, general and special, and in the public service of the country, in order that they might be used for the national good. A discussion in the House of Commons had that morning impressed on his mind the importance of a subject which he thought was only being glanced at for the first time—viz., the value of organised effort to direct young people into the industries for which they were best fitted. The volume of disease which must arise year by year through people predisposed to certain diseases entering industries for which they were unsuited must, he said, be appalling, and it was only by the organisation and correlation of the work of the medical profession and by transmitting the resulting knowledge to the Government of the country that we could hope even to get to the threshold of that better national organisation which would enable us to use our national stock of health to the utmost.

Sir William Joynson-Hicks, who proposed the toast of the Federation, said that the whole idea of caring for the public health was a product of recent times; the old system was remedial, to-day it was preventive. All our factory legislation, a great deal of our mine legislation, the inspection of every kind of institution, the medical care of our sailors and soldiers, and all forms of sanitation, had arisen more or less definitely during the last 25 years, and we had to realise that that great work which had begun and which had been continued so successfully was progressing in an ever-increasing degree. Public opinion was now ripe for increased action in all the directions he had referred to, as well as in the work of the welfare of children, and in the whole position of the maternity question because politicians were now beginning to realise the raw material value of human life. Do you know, he asked, what it costs to produce a man? No man or woman in this country who reaches the age of 21 was produced for less than £500, and a skilled workman was worth £5000 at the lowest estimate; yet we were allowing these men to slip through our fingers. They represented the best capital of the nation, and yet many were allowed to contract every kind of disease and thus render themselves unfit to carry on their work or to make themselves a profitable commodity for the great community which had given them birth. That was the problem the Federation was called upon to deal with, and would be called upon to deal with still more in the next few years. The casualties of peace were greater than the casualties of war. To take an example, the disease of tuberculosis claimed roughly 1000 fatal casualties per week, and it would be worth untold wealth and effort to get rid of a disease of that kind. They who were, or who might be, responsible to the Government of the nation looked to the Federation to help them in dealing with the prevention of disease, as well as with the important question of insurance. The medical profession were brought into more direct contact with the people than were the Ministers of the Government, and some kind of liaison was wanted. That liaison was formed by the Federation.

Sir Thomas Horder, chairman of the Executive Council, who responded, paid a warm tribute to the memory of his predecessor, the late Sir Malcolm Morris. The aims and ideals of the Federation, he said, were warmly approved by past and present Ministers of Health, and he might perhaps even speak of the future, for possibly a future Minister of Health was among them. As chairman of the executive body he said that the course before them was that of individual effort, by which alone in the early days potential assets can be converted into realities.

Capt. Elliot then proposed the Health of the Guests, coupling with the toast the name of Mr. St. Loe Strachey, the editor of the *Spectator*.

Mr. Strachey, in reply, interested the audience with an appreciation of the wonderful intuition displayed by Shakespeare in his description of the medical mind and medical attitude. He gave definite reasons for holding that Shakespeare must have been acquainted with the writings of Hippocrates, and particularly with the famous Hippocratic Oath.

At intervals during the evening Mr. Frederick Dawson played delightfully upon the piano.

IRELAND.

(From our own Correspondent.)

The Irish Medical Association.

The postponed annual general meeting of the Irish Medical Association was held in the Royal College of Surgeons in Ireland on June 18th. Senator W. O'Sullivan, the President, was in the chair, and delivered an address. He said that at the moment there were being discussed different matters of much concern to the Irish medical profession. One of these was the question of medical legislation, and another the question whether or not there should be a separate Medical Council for education and registration for the Irish Free State. With regard to this latter question, an attitude of insularity or intensive nationality would be disastrous, and it was hoped that when this question came to be settled the present relations of the country with the General Medical Council would be altered as little as possible. However, some devolution of functions, especially with respect to penal administration, might be of advantage to both countries. He expressed his regret that up to the present the claims of the medical profession had received little recognition from the Ministry of Local Government. Indeed, when a Local Government Bill was being passed through the Dail it was made the occasion to repeal those clauses of the Local Government Act of 1919 which provided for a compulsory pension for dispensary doctors. The Local Government Bill, for the most part, lacked any medical conception. Even if the Bill's public health provisions had become law, it might happen that they would be departmentally nullified by the offer of salaries so inadequate that they could only ensure the inaction of the medical officials appointed to administer the Act. At the close of his address the President moved the following resolution, which was passed unanimously: "That this meeting expresses the hope that no change will be made in the system of medical registration in the Irish Free State which would interfere with the right already possessed by medical men qualified in Ireland to practise in Great Britain and the Dominions."

The President stated further that the Government had under consideration the question of transferring medical appointments from the local authorities to a central appointments board. Several members expressed disapproval of such a proposal, and the following resolution was unanimously carried: "That this Association re-affirms its opinion that a National Medical Service should be established for the Irish Free State, entrance being by competitive examination, and as recommended by the Irish Public Health Council." A resolution was also passed protesting against the hardship imposed on medical practitioners, who used motor-cars as instruments of their profession, by the present excessive taxation.

INDIAN MEDICAL SERVICE:
ANNUAL DINNER.

Ninety-two officers of the Indian Medical Service sat down to the annual dinner at the Trocadero, London, on June 18th. Colonel J. J. Pratt occupied the chair, and the other members present were as follows:—

Major-Generals: Sir R. H. Charles, G.C.V.O., K.C.S.I.; T. Grainger, C.B.; G. F. A. Harris, C.S.I.; Sir P. Hehir, K.C.I.E., C.B., C.M.G.; H. Hendley, C.S.I.; J. B. Smith, C.B., C.I.E.

Air-Commodore D. Munro, C.B., C.M.G.

Colonels: J. Crimmin, V.C., C.B., C.I.E.; C. M. Goodbody, C.I.E., D.S.O.; T. A. Grainger, C.M.G.; C. R. M. Green; A. J. Macnab, C.B., C.M.G.; H. K. McKay, C.B., C.I.E.; H. Austen Smith, C.I.E.; T. Stodart, C.I.E.; R. G. Turner, C.M.G., D.S.O.; C. N. C. Wimberley, C.M.G.

Lieut.-Colonels: A. Alcock, C.I.E.; J. Anderson, C.I.E.; G. T. Birdwood; A. W. Cook-Young; D. G. Crawford; J. M. Crawford, O.B.E.; H. M. Cruddas, C.M.G., O.B.E.; R. H. Elliot; Sir T. J. Carey Evans, M.C.; F. F. Elwes, C.I.E.; J. Entrican, C.I.E.; A. M. Fleming; J. K. S. Fleming, O.B.E.; A. B. Fry, C.I.E., D.S.O.; H. Greany; J. W. Grant; E. C. Hodgson; E. V. Hugo, C.M.G.; J. G. Hulbert; C. H. James, C.I.E.; J. G. Jordan; H. C. Keates; R. S. Kennedy, D.S.O., M.C.; H. Kirkpatrick; J. C. G. Kunhardt; Clayton Lane; W. B. Lane, C.I.E., C.B.E.; J. Lloyd-Jones; R. McCarrison, C.I.E.; J. McC. A. Macmillan; H. M. H. Melhuish, D.S.O.; A. Miller; R. K. Mitter; T. R. Mulroney; F. O'Kinealy, C.I.E., C.V.O.; S. E. Prall; J. W. F. Rait; Sir J. R. Roberts, C.I.E.; Sir L. Rogers, C.I.E.; R. Steen; A. Street; C. Thomson; W. H. Thornhill; G. Tate; J. H. Tull Walsh; H. J. Walton; D. P. Warliker; C. G. Webster; R. T. Wells; C. E. Williams; H. R. Woolbert; A. C. Younan; T. C. McC. Young.

Majors: H. C. Brown, C.I.E.; H. J. M. Cursetjee, D.S.O.; W. J. Fraser; D. L. Graham, O.B.E.; N. H. Hume; L. C. Irvine; E. O'G. Kirwan; P. S. Mills; W. S. Nealor; A. N. Palit; M. L. Puri; M. J. Quirke; J. G. B. Shand; H. H. Thorburn, C.I.E.

Captains: N. Briggs; J. C. De; G. Kumar; J. G. McCann; V. R. Mirajkar; S. Nag; V. S. R. Pandit; R. Sweet, D.S.O.

VOCAL THERAPY SOCIETY CONCERT.—The members of the King's Services Choirs, with the foundation of which the largest share was taken by Lady Carnarvon, gave their fifteenth concert at the Chelsea Polytechnic Institute on June 14th. The men are sufferers from shell-shock in its various forms, and are beneficially affected by choral singing with the deep-breathing which it involves. Although in time the number of recoveries will result in a diminution of strain on the society's resources, there is still a great deal for it to do, and it is to be hoped that it will receive every support. Those interested in such sufferers should take opportunity of attending some of the concerts.

Correspondence.

"Audi alteram partem."

SOME FUNDAMENTAL FACTORS IN THE SPREAD OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—In his suggestive and interesting paper on this subject, published in THE LANCET of June 7th, Prof. S. F. Dudley makes certain statements which I am surprised to read, and with which I feel compelled to disagree most strongly. The statements I refer to are contained in the following sentences: "The short-range jet of heavy droplets is the usual means by which so-called 'contact' infection is acquired. The best example of the practical application of this principle is seen in the 'bed-isolation' treatment of infectious diseases. Owing to the impossibility of throwing a heavy dose of infective material more than a few feet it is possible to nurse two or three different infectious diseases in the same ward without any appreciable danger from cross-infection, provided the beds are far enough apart." If Prof. Dudley had qualified the statement by saying that it is possible so to nurse certain different infectious diseases, or if he had specified the two or three infectious diseases which could be so nursed, I do not think I should quarrel with the statement. But as it stands it implies (1) that several infectious diseases, no matter what their nature, can be safely nursed simultaneously in the same ward, and (2) that infection is to all intents and purposes always conveyed by heavy droplets with a short range. As regards (1), I venture to say that if Prof. Dudley will read the papers and reports of discussions on the subject of bed-isolation which have appeared in THE LANCET during the last two or three years he will amend his statement at any rate to the extent I have suggested; as regards (2), I say without hesitation that what is stated has not been proved. Prof. Dudley may possibly reply that so-called "contact" infection only is referred to. I confess, however, that I do not understand by "contact" infection infection which is conveyed by droplets through the air, however short the striking distance may be; but if "contact" infection is to include droplet-infection with a short range, then I must demur to the implications that in a bed-isolation ward infection is conveyed by contact only and not through the air, and that droplet infection cannot be effective at comparatively long distances. It may be so in certain cases of certain infectious diseases—e.g., diphtheria and scarlet fever—but for such diseases as measles, small-pox, and chicken-pox, it has not been proved to be so, and, indeed, clinical experience is to the contrary.

I am the more surprised at Prof. Dudley's statements because he has more than once in his paper mentioned the fact that micro-organisms can be conveyed through the air in a ward for 30 or 40 feet. It is true that he explains that infection is rarely effective at those distances, because the droplet which can be carried so far is small, and therefore the dose of infecting virus is small. But is that true? Is it even "the case with many diseases and under ordinary conditions of ventilation," as Prof. Dudley says it is? It may, for all we know, be a question of the size of the infecting organism, concerning which Prof. Dudley says nothing. His experience in the boys' school has been chiefly with the diphtheria bacillus, which is comparatively a large organism. Of the micro-organisms of measles, small-pox, and chicken-pox we know nothing, except that that of measles is stated to be a filter-passer and must therefore be minute. A small droplet might contain many minute organisms, and be as infective as a large one containing many large.

I wish to draw special attention to this question because it is of considerable practical importance, and because I think that Prof. Dudley's statements are likely to be misunderstood by those who are lacking in the necessary administrative experience and are ignorant of the problems of infection with which he is dealing. May I add a few words on one or two points of, at present, hypothetical interest?

In his discussion of the questions of dosage and velocity of infection it seems to me that Prof. Dudley has forgotten one factor which should be introduced into his formula, and that is the faculty the micro-organism has of reproducing itself rapidly. Thus, supposing that the minimal infecting dose is 100, and that the animal attacked can deal with the micro-organisms at the rate of 50 per hour, will the 50 that have not been killed at the end of the hour have multiplied or not? If they have, then there will be an indeterminate number for the attacked animal to deal with, in addition to the 50 surviving from the original invaders, and they must be taken into account in any formula such as Prof. Dudley gives.

To me the most interesting parts of Prof. Dudley's paper are those dealing with host-resistance, epidemic immunity, and the variation of parasitic virulence. I confess to being one of those who find a powerful factor in this variation. Prof. Dudley does not in so many words define what he means by virulence; but towards the end of his paper he suggests that the word may be used to mean power on the part of the micro-organism to injure rather than to kill its host with a small single dose; and, again, he says that "the fact of not being able to detect variation in killing power of a parasite is no argument against some change having occurred in its power of producing disease." He is, I take it, driven to this statement because in diphtheria, the disease on a study of which he seems to have based most of his conclusions, the bacteriologists have not been able to show any but a very transient variation in the virulence of the causal organisms. But I quite agree with his general conclusion. Without postulating the existence of two faculties, an infecting and an injuring, I find it difficult to explain more than one epidemiological fact—for instance, the epidemiological behaviour of scarlet fever over a long period of years. If I remember rightly (for at present circumstances prevent me from referring to books or notes), the subject was discussed at a meeting of the Section of Epidemiology and State Medicine of the last International Medical Congress held in London in 1913. The occasion was a paper by Dr. Major Greenwood on certain epidemiological principles. I must not, however, be supposed to suggest that these two faculties are evident in all infectious diseases, or that the variation in power of resistance of the persons attacked is without effect. Indeed, such evidence as is afforded by the results of the Schick reaction is in favour of the existence of this variation not only at different ages, but in different classes of the community. Perhaps workers in the future may be able to show by a wide application of the Schick, and possibly similar tests, whether the condition of the community in respect of susceptibility has also a secular variation.

I am, Sir, yours faithfully,

E. W. GOODALL.

North-Western Hospital, Hampstead, N.W.,
June 19th, 1924.

"INDUCTION" OR "CAUSE" OF CANCER.

To the Editor of THE LANCET.

SIR,—In his last letter Sir Lenthal Cheatle has treated us to a gay little essay on the proper use of the terms "cause" and "induce." With his use of the latter, I imagine, no logician or literary stylist would quarrel. Being neither, I venture with great humility to suggest to him that, in the two sentences in which it occurs, the noun "cause" is not *le mot juste*, and that if he were to substitute some other word for it he might more lucidly express whatever meaning he intends to convey. I am eagerly awaiting his attempt to find six diseases which can be induced by something that does not cause them.

Dr. H. M. Woodcock has been giving an airing to his delicate outcross ewe lamb—"hæmatophagy." There used to be a story amongst photographers of a great authority who wrote much and learnedly on photographic technique. It was said that when he was about to be married some friend presented him with a camera. He gave up writing and spent the rest of his life trying to take a photograph. I should love to witness the profound emotion with which Dr. Woodcock will behold his first case of cancer.

I am, Sir, yours faithfully,

London, June 20th, 1924. ARCHIBALD LEITCH.

To the Editor of THE LANCET.

SIR,—There are one or two points, by no means novel, that are perhaps worth while bearing in mind during discussion of causation. When, in speaking of any particular observed sequence, we impute or allege a causative action in respect of the antecedent or antecedents, we are not referring to what we have observed, but to a subjective gloss we have placed on what has been observed. We impute to the antecedent and consequent of the sequence the "causal" relation that we think we recognise between our desires and our actions. Moreover, when we single out a particular antecedent and distinguish it from its fellows by calling it "the" cause of what follows, we are not recognising any objective peculiarity; we are merely, as Dr. Mercier used to say, considering as "the" cause that which most interests us, or which we think the most important. There is no harm in all this so long as we recognise what we are doing, but when we speak as if a causal relation could be observed in the same way as we can observe a maiden aunt, why then we are on a fair way to become modern "scholastic realists."

But in medicine (and in surgery!) we do not stop even at this point. We go on to impute causal relations, not merely in respect of particular observed sequences, but in respect of purely fictitious or conceptual sequences. For "diseases" are but universals, or mental constructs, and are not objects of perception. When, therefore, we speak of the cause of cancer we are in the world of *ficta*, as William of Ockham would have said; in the world of fictitious entities, as Bentham did say; in the world of "as if," as Vaihinger does say. Again, there is no harm, and a great deal of advantage, in so speaking: so long, that is, as we recognise what we are doing. But when we declare that because a specific disease, like cancer, can have only one cause, and that a specific one, certain things follow; we are mistaking convenient fictions for statements that can be verified by direct observation. In the world of fictions, or concepts, these single causes of diseases—like the tubercle bacillus in respect of tuberculosis—stand really for defining notions. We define tuberculosis as the disease "caused" by the tubercle bacillus, and think we have dodged the *circulus in definiendo* by our adroit use of the word "caused." We are subconsciously aware that, in the world of happenings, single causes, or specific causes, do not exist objectively as such; and so we try to make an adjustment by talking of predisposing *versus* exciting causes, of induction and not of causation, and the like, without defining our terms or saying what we mean.

An enormous amount of controversial error and of confusion in practice disappears as soon as we recognise the validity of the conceptualism taught by a whole series of thinkers, from Ockham to Vaihinger, or, if we prefer it, the theory of symbolism as set out lately in "The Meaning of Meaning," by Messrs. Ogden and Richards.

I am, Sir, yours faithfully,

F. G. CROOKSHANK.

Wimpole-street, W., June 21st, 1924.

SPINAL ANALGESIA.

To the Editor of THE LANCET.

SIR,—Mr. Holroyd Slater's interesting account of his experiences with spinal analgesia (THE LANCET, June 21st, 1924, p. 1256), in general, agrees with the observations of other workers. Nevertheless, on one or two points, I think Mr. Slater's opinions are open to criticism.

1. Mr. Slater states that he knows of no disadvantages in the procedure, provided that the technique be correct, and that only one of his cases, a nurse, complained of headache. May I remark that the coöperation of the patient is essential, but not always obtainable; that the fall in blood pressure, which Mr. Slater acknowledges to be the rule, is sometimes so considerable as to determine the death of a patient, if already deeply shocked; that neurologists describe a condition which they term "stovaine ataxia"; that some patients suffer from slight backache for several months after the injection; and that most observers confess to severe post-operative headache in at least 5 per cent. of their cases. It is true that the headache may be prevented to some extent by reducing the escape of cerebro-spinal fluid, by keeping the patient still, and by attention to other details, but physicians agree that simple diagnostic lumbar puncture often gives rise to distressing and intractable headache. Together with F. S. Rood (THE LANCET, 1919, i., 14), and others, I have found headache to be very rare after the administration of a general anæsthetic with spinal analgesia. Another objection to the method is the risk (though it should be small) of infection of the meninges, or of injury to the cauda equina by the needle itself, or by intraneural injection of the solution.

2. While quite in agreement with Mr. Slater's views on the value of spinal analgesia in operations on the pelvic organs, perineum, and lower limbs, I have seen severe shock and vomiting during manipulation of the small bowel, mesentery, or stomach, notwithstanding that analgesia extended above the costal margin, and there was complete paresis of the abdominal wall. I have often seen simple hysterectomy performed under spinal analgesia, without undue shock, but in the presence of adhesions separation of the uterus from coils of small bowel always gives rise to some degree of syncope. I attribute this to the difficulty of blocking sensory sympathetic impulses from stomach and bowel unless analgesia extend to the region of the upper dorsal spinal nerves, with attendant grave fall of blood pressure and undesirable paralysis of the intercostal muscles.

3. Surely, Mr. Slater cannot be quite certain of his ground when he states that "the Trendelenburg position cannot be employed with safety." During the past few years all authorities have agreed that, provided ten minutes has elapsed since the injection of the drug, the drug is fixed, and ill-effects from the complete Trendelenburg position are almost unknown. I have notes of 100 consecutive successful cases of this class. It should be remembered that the flow of cerebro-spinal fluid is from the cranium to the sacrum.

With Mr. Slater I, too, have found spinal analgesia of great value in operations involving the lower limbs and the pelvic contents, and I consider the method is specially indicated in the presence of disorders of metabolism, such as diabetes and toxæmias of pregnancy, of nephritis, of heart disease, and for Cæsarean section. Under spinal analgesia, in combination with gas and oxygen, severe procedures, including Wertheim's hysterectomy and excision of the rectum or of a portion of the large bowel, can be undertaken with minimal risk. But to my mind there should be more discrimination in Mr. Slater's advocacy of spinal analgesia.

I am, Sir, yours faithfully,
HENRY FEATHERSTONE.
Birmingham, June 23rd, 1924.

A COUNTY VENEREAL DISEASES SCHEME.

To the Editor of THE LANCET.

SIR,—My attention has been directed to the letter from Dr. W. Herbert Brown, of Glasgow, in your issue of June 7th last, regarding the statistical tables incorporated in my paper on the above subject, which was read at the Imperial Social Hygiene Congress at the British Empire Exhibition. The "headings" of my tables, to which Dr. Brown takes exception as "misleading and in part valueless," are those used in the official returns issued annually from 1918 to 1923 by the Ministry of Health to medical officers of treatment centres, and the "notes" on these returns refer medical officers to Memo. V.21, issued by the Ministry, which contains "suggestions as to the tests which should have been applied before patients who have been under treatment for syphilis or gonorrhœa are regarded and classified as 'discharged after completion of treatment and observation.'"

I am, Sir, yours faithfully,
J. J. BUTTERWORTH,
Medical Officer of Health, Lancashire County Council.
June 18th, 1924.

THE SCHICK TEST.

To the Editor of THE LANCET.

SIR,—We much regret that in our paper on the Schick Test in THE LANCET of May 31st, we have misrepresented the views of Dr. R. A. O'Brien regarding the significance of pseudo-reactions. We attributed to him the suggestion that pseudo-reactors were immune, both of us having, it would appear, misread a sentence in one of the many helpful letters we received from him during our investigation of the test. We must confess, however, that the error is inexcusable, as Dr. O'Brien's published papers make it clear that he can never have held such an opinion. That being so, we can only offer him our sincere apologies.—We are, Sir, yours faithfully,

CLAUDE B. KER,
JOHN MCGARRITY.
Edinburgh, June 18th, 1924.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 14TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week—namely: small-pox, 56; scarlet fever, 1294 (as against 1334 of the previous week); diphtheria, 616; enteric fever, 83; pneumonia, 588 (as against 742 of the previous week); puerperal fever, 44; cerebro-spinal fever, 7 (as against 3 of the previous week); acute poliomyelitis, 5; acute polio-encephalitis, 2; encephalitis lethargica, 171 (as against 179 of the previous week); dysentery, 10; ophthalmia neonatorum, 122. There were no cases of cholera, plague, typhus fever, or continued fever notified during the week. Of the 56 cases of small-pox, 26 were notified from the county of Derby (Derby 5, Chesterfield 17, Chesterfield R.D. 4); 12 from Yorks, North Riding (Middlesbrough); and 6 from Northumberland (Ashington). Of the cases of encephalitis lethargica, 33 were from the County of London (Bethnal Green 1, Deptford 3, Greenwich 2, Hackney 1, Hammersmith 1, Hampstead 1, Islington 3, Kensington 1, Lambeth 2, St. Pancras 5, Southwark 2, Stepney 7, Stoke Newington 2, Wandsworth 1, Woolwich 1); 9 from the county of Durham; 7 from Essex; 8 from Bristol; 18 from the county of Lancaster (Bolton 3, Liverpool 4, Manchester 3); 7 from Middlesex, 7 from the county of Stafford; 6 from Surrey; 10 from Warwick (Birmingham 6); 5 from Yorks, E. Riding (Hull 4); 11 from Yorks, West Riding (Sheffield 6).

Deaths.—In the aggregate of great towns, the deaths from influenza fell further from 46 to 25. The deaths from diphtheria have increased from 8 to 14 in London and from 17 to 27 in the great towns.

THE Minister of Health has appointed Mr. S. F. Perry, M.P., Parliamentary Private Secretary (unpaid).

AT the fiftieth annual meeting of the American Neurological Association, held at Philadelphia on June 5th–7th, Sir James Purves-Stewart was elected an Associate Member.

Medical News.

Society of Apothecaries of London.—At the examinations held recently the following candidates were successful:—

Surgery.—F. James (Guy's), R. D. M. Tims (Cambridge and St. Thomas's).

Medicine.—K. R. Chaudhri (St. Mary's), H. T. Chiswell (Guy's), C. E. Donaldson (Camb. and St. Mary's), A. Kotbi (St. Mary's).

Forensic Medicine.—W. Bentley (Birmingham), H. P. Burns (St. Mary's), K. R. Chaudhri (St. Mary's), A. Kotbi (St. Mary's), J. Wilson (Leeds).

Midwifery.—R. D. Jones (Edin. and Middlesex), W. R. A. Line (Birm.), M. Schwartzman (Odessa and Middlesex), J. Wilson (Leeds).

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: H. T. Chiswell, F. James, A. Kotbi, and W. R. A. Line.

London Hospital Medical College.—The distribution of prizes to the students will be made in the Library of the College, Turner-street, Mile End, by Sir Arthur Keith, on Monday, June 30th, at 3.30 P.M.

Selborne Society: Lectures for Schools.—The Selborne Society, one of whose excellent objects is to bring about public appreciation of the value of science to the community, has for the past ten years systematically sent out lecturers to societies and schools. The current list includes lectures on the Growth of Towns, Wanderings in Zoo Land, Scientific Developments of the World's Food-Supply, Bacteria, and the Ductless Glands. Copies of this list can be obtained from the Assistant Secretary of the Society, at The Hermitage, Hanwell, London, W. 7.

Medico-Psychological Association.—According to the revised agenda of the eighty-third annual meeting of the Association, announced in our issue of last week, Dr. F. R. Martin will read his paper entitled the Reaction of the Blood to the Ingestion of Protein in the Psychoses on July 2nd at 11.30 A.M., not on July 1st as stated. On July 2nd, at 1 P.M., the presidential address will be delivered by Dr. M. J. Nolan. On July 3rd, in addition to the papers already mentioned, Dr. W. M. McAlister will read a paper on the Therapeutic Action of Inoculation with Malaria, and Dr. Marion Alexander will give a communication on Lilliputian Hallucinations, with Notes of a Case. A demonstration of various pathological specimens will be on view.

Departmental Committee on Hospital Services in Scotland.—The Scottish Board of Health has appointed a committee to inquire into and report upon the extent and nature of the inadequacy of the present hospital and ancillary services in Scotland, and to make recommendations for the development and maintenance of those services to meet the needs of the community. The personnel of the committee is as follows:—Lord Mackenzie (chairman), Sir Norman Walker, Dr. D. J. Mackintosh, Mr. T. J. Addly, Mr. John Birnie, Dr. R. C. Buist, Dr. A. K. Chalmers, Mr. John S. Doeg, Mr. Russell Paton, Mr. James Robertson, Mrs. Elizabeth Shirley, and Mr. Joseph Waugh. All communications on the subject of the committee should be addressed to the secretary, Mr. Niven McNicoll, of the Scottish Board of Health, Edinburgh.

Royal Medical Benevolent Fund.—At the last meeting of the Case Committee 26 cases were considered and £351 10*s.* voted to 23 applicants. The following is a summary of the new cases relieved:—

Widow, aged 51, of M.D. Irel., 1875, who practised in London and died in 1923. When applicant's husband died after a long illness the capital was reduced to £47. The practice was sold for £85. Applicant managed to pay up all outstanding bills and put £70 away to meet school fees for her two youngest children. The only money coming in is from the two daughters who are governesses and they allowed their mother 32*s.* 6*d.* per week, but £1 of this ceased on May 31st as the eldest girl's post lapsed, owing to the child being sent to school. Applicant earned £6 10*s.* by cooking. Voted £20 in two instalments.

Daughter, aged 65, of M.R.C.S. Eng. who practised in Chelsea and died in 1885. Applicant is the eighth daughter of 11 children, and up to 1919 supported herself, but owing to the war the firm closed down. Unable to obtain another post owing to age. Now lives with a married sister and helps her in the house, but this sister can ill afford to keep her. A small grant was made and case to be reconsidered.

Widow, aged 60, of L.S.A. who practised in Devon and died in 1905. Applicant asks the Fund to help her to meet her expenses as her total income is only £63 and her rent 10*s.* per week. Owing to ill-health she is quite unable to work to augment her income. Voted £12 in 12 instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, K.B.E., C.E., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

Dr. R. A. Lyster, county medical officer of health for Hampshire, has been elected President of the Society of Medical Officers of Health.

Society for the Study of Inebriety.—The annual meeting of this Society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on July 8th, at 4 P.M. A short presidential address on the Aims and Work of the Society for the Study of Inebriety will be delivered by Sir William Willcox, after which a discussion will be opened by Dr. Walter Asten, on the Institutional Treatment of the Alcoholic Inebriate and the Drug Addict.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, June 18th.

Cost of Health Insurance Administration.

Mr. Trevelyan Thomson asked the Minister of Health what was the cost of central administration of National Health Insurance benefits per insured person—i.e., by the Ministry of Health, the Welsh Board of Health, and the Scottish Board of Health, respectively.—Mr. Wheatley replied: The cost of central administration of National Health Insurance in the year 1923 per insured person was as follows: Ministry of Health, 1*s.* 4*d.*; Welsh Board of Health, 1*s.* 9*d.*; Scottish Board of Health, 1*s.* 4*d.*

Housing and Slum Clearance Schemes.

Captain Elliot asked the Minister of Health how many houses were at present under construction by local authorities under the Housing Acts, 1919–23, and slum clearance schemes, respectively; and for how many had schemes been approved under these respective heads on which work had not yet commenced.—Mr. Wheatley replied: The position of local authorities' housing schemes under the Housing Acts of 1919 and 1923 on June 1st was as follows:—

	Housing Acts of—		
	1919.	1923.	Total.
Number of houses under construction	2931	12,752	15,683
Number of houses in approved schemes not yet commenced ..	305	30,900	31,205

As regards slum clearances schemes have been approved which will involve the provision of approximately 5894 houses; tenders have been approved covering 1090 houses.

Captain Elliot further asked the Minister of Health how many houses were at present under construction by private enterprise on schemes under the Housing Act, 1923; and how many houses had been approved in schemes on which work had not yet commenced.—Mr. Wheatley replied: 26,750 houses were under construction on June 1st by private enterprise in connexion with schemes approved under the Housing, &c., Act, 1923, and a further 56,660 had been approved but not commenced at that date.

Sick-Berth Staff at Portland Hospital.

Sir Thomas Bramsdon asked the Parliamentary Secretary to the Admiralty if he would state the number of chief sick-berth petty officers, sick-berth petty officers, and leading and sick-berth attendant ratings now employed at the Royal Naval Hospital, Portland; and if he was aware that dissatisfaction existed with regard to the amount of leave these ratings were able to obtain, on account of the shortage of staff, as compared with other ratings of equal status in the port.—Mr. Ammon replied: The numbers asked for in the first part of the question are 1, 3, 5, and 9 respectively. With regard to the second part of the question, I am not aware that there is any dissatisfaction, but leave is more difficult to arrange at small hospitals than at large ones. The matter was carefully considered as the result of a welfare request in 1922, and it was found that the circumstances did not justify any increase of complement.

Naval Ratings and Tuberculosis.

Sir Bertram Falle asked the Parliamentary Secretary to the Admiralty what percentage of naval ratings invalided during the year 1923 owing to tuberculosis was attributable to service and what percentage was considered to be not attributable to service.—Mr. Ammon replied: The percentages of attributable and non-attributable tuberculosis invalidings during the year in question were 2·1 and 97·9 respectively.

Women as Medical Officers.

Mr. Costello asked the Minister of Health to state what was the total number of medical officers of health employed by local authorities in England and Wales; what was the total number of assistant medical officers of health and school medical officers so employed; how many of these were men and how many women; and in how many cases, during the past 12 months, upon vacancies arising for assistant medical officers in posts held by women, the women had been replaced by men.—Mr. WHEATLEY replied: The total number of medical officers of health employed by local authorities in England and Wales is 1455, all of whom are men. I have not complete information as to the numbers of assistant medical officers of health, but the available records indicate that the number of such officers in England giving whole or part time to maternity and child welfare services is 227, of whom approximately half are women; to tuberculosis services 76, of whom 9 are women; to venereal disease services 42, of whom 12 are women. Many assistant medical officers of health are engaged on more than one service, and therefore these figures are not mutually exclusive; nor do they include certain medical officers appointed wholly for special services. Corresponding figures are not available as to Wales. There are employed in England and Wales 317 school medical officers and 710 assistant school medical officers; of these, 826 are men and 201 are women; 286 school medical officers and 341 assistant school medical officers also carry out public health duties. During the last 12 months I am aware of one vacancy in the post of assistant medical officer of health, and one in the post of assistant school medical officer, previously held by women which have been filled by men.

Sale of Milk in Restaurants.

Mr. LAMB asked the Minister of Health whether he was aware of the practice of exhibiting notices in restaurants and cafés stating that milk was supplied without any guarantee that it was new, pure, or with all its cream; and whether he proposed to secure an amendment of the law to prevent this evasion of the Sale of Food and Drugs Act.—Mr. WHEATLEY replied: Yes, Sir. I am aware of the practice, but I am afraid I cannot undertake to introduce legislation for the amendment of the Sale of Food and Drugs Act at the present time.

Small-pox Hospitals for Tuberculous Patients.

Mr. BLACK asked the Minister of Health the number of small-pox hospitals in Great Britain; how many of these hospitals were unused by patients suffering from the disease in each year from 1914 to 1923; and whether he would consider the desirability and economy of using these hospitals when unoccupied for the treatment of tuberculosis, subject to an arrangement with the county councils for the evacuation of the tuberculous patients at 48 hours' notice in the event of the outbreak of a small-pox epidemic and the premises being required for small-pox patients.—Mr. WHEATLEY replied: There are approximately 340 small-pox hospitals in England and Wales. I have no precise information as to the number of these hospitals which were not used for small-pox cases in each of the past ten years, but about 80 were so used last year. Whilst I should be prepared to consider proposals for the use of small-pox hospitals for the treatment of tuberculosis, I must point out that many of these hospitals are not suitable for the reception of tuberculous patients, and that for the protection of the public health it would not be sufficient merely to require evacuation of the tuberculous patients at 48 hours' notice, unless some alternative accommodation were available for the isolation of the first cases of small-pox.

Spirochætosis Ictero-hæmorrhagica in East Lothian.

Mr. CLARKE asked the Under Secretary to the Scottish Board of Health if, as the result of his inquiries into the cause of the outbreak of spirochætosis, or rat poison, in the East Lothian coalfield, he was yet in a position to state whether or no he would hold a public inquiry so as to allay the anxiety among the people in that district.—Mr. STEWART replied: I am informed that the Mines Department are in communication with the Medical Research Council, with a view to research into the character of the disease. Until further scientific information is available it is considered that a public inquiry would not serve any useful purpose.

THURSDAY, JUNE 19TH.

The Spahlinger Treatment.

Mr. CECIL WILSON asked the Minister of Health whether any progress was being made with the Spahlinger treatment, and how the matter now stood.—Mr. WHEATLEY replied: So far as I am concerned this matter stands as it did on April 16th, when I stated, in reply to a question, that I am anxious to arrange for a scientific investigation of this method of treatment in this country as soon as the materials were made available, and had personally given Mr. Spahlinger assurances to that effect.

Consultative Health Councils.

Mr. MCENTEE asked the Minister of Health why the Consultative Councils authorised by the Ministry of Health Act to advise him upon matters of public health administration relating to medical and allied services, local health administration, and general health questions had not met since 1921; and whether, owing to lack of interest in their work, he was prepared to dissolve such councils and reconstitute them from bodies closely concerned and taking an active interest in health matters.—Mr. WHEATLEY replied: Meetings of these bodies have not been held since the date named because no questions have arisen upon which the Minister of Health has considered it desirable to ask for their advice. The principal suggestion in the latter part of the question was followed in constituting these bodies, and provision is made for periodical variations in their membership.

Certificates in Medical Electricity.

Mrs. WINTRINGHAM asked the Minister of Pensions whether he was aware that the massage advisory committee recently made a unanimous recommendation that the payment of moneys granted for the extra certificates in medical electricity and Swedish remedial exercises be made to all masseuses holding these certificates, and that the reservation limiting such allowances to masseuses engaged in the work requiring the certificates be annulled; whether the Ministry had taken any action on the resolution; and, if not, whether it intended to do so.—Mr. F. O. ROBERTS replied: The reply to the first part of the question is in the affirmative. As regards the latter part, I would draw attention to the fact that the Civil Service Arbitration Board agreed to their award of May 22nd, 1922, that payment of allowances for additional certificates should be made only when the masseurs or masseuses were required to render the forms of treatment in which such certificates indicate that they are proficient, but I am considering the whole question raised in the light of present circumstances.

Deaf Children.

Mr. ROBERT MORRISON asked the President of the Board of Education the number of deaf children of school age in England and Wales, and the number of these who were being taught in special schools or special classes for the deaf.—Mr. TREVELYAN replied: The approximate number of deaf children in England and Wales is 5700, of whom it is estimated that about 1600 are only partially deaf. The recognised accommodation for these children in special schools or classes for the deaf is 4582, and the number of children who were attending these schools on March 31st, 1923, the latest date for which complete figures are available, was 4041.

FRIDAY, JUNE 20TH.

Protection from Lead Poisoning.

Mr. R. DAVIES, Under Secretary to the Home Office, moved the second reading of the Lead Paint (Protection against Poisoning) Bill. He explained that the measure had been framed in accordance with the agreement arrived at by a conference of the International Labour Organisation at Geneva, and the Government would regard it as a breach of honour and a betrayal if the House did not give the Bill a second reading. When old lead paint was rubbed down with sandpaper dust was produced which was specially dangerous indoors where there was not a free flow of air. The painters, masters and men, were unanimously in favour of the Bill. The people engaged in the production of white lead were opposed to the measure, but the voice of the painters who suffered from its use was, he thought, entitled to greater weight. From 1910 to 1923 there came to the notice of the Factory Department in respect of house painters 1500 cases of lead poisoning, of which over 300 were fatal. The trade would be allowed three years to adjust itself to the new conditions. It had been suggested that if a waterproof sandpaper were used wet to rub down paint all would be well, but the Home Office experts were satisfied that this plan did not meet the case. Czecho-Slovakia, Esthonia, and Sweden had formally ratified the Convention, and ratification had been authorised by Austria, Greece, Italy, and Holland. The fundamental principles of the Bill were that after Nov. 19th, 1927, it would not be lawful to use lead paint in painting any part of the interior of a building, and that the employment of women and young persons in painting any part of a building with lead paint should be prohibited.

Mr. HARNEY moved the following amendment: "That this House, whilst of opinion that it is premature to commit Great Britain to the ratification of the International Labour Organisation Convention of Nov. 19th, 1921, and to the prohibition of the use of lead paint in internal painting, would welcome the immediate introduction of a Bill for the better regulation of the use of such paint." He claimed that prohibition would throw thousands out of employment and compel the community to use an inferior article.

Mr. Grenfell suggested that it would be better to leave the whole question open until 1927. If the Bill passed as it was the disease would still increase, not because there would be more disease, but because more pains were being taken to discover it.

Mr. Raynes, who said he was the only operative painter in the House, admitted that there had been a continuing reduction in the number of cases of poisoning by lead paint, but that process was, nevertheless, one of the root causes of industrial disease which it was their duty to abolish. It was practically impossible to make any regulations which would be effective. The hon. Member said that his own right hand (which he raised for the inspection of the House) was for six months each year during ten years useless for writing owing to lead poisoning.

Mr. Bridgeman, a former Home Secretary, supported the amendment. The regulations, he said, should be brought into operation at once. Meantime there might be some invention that would safeguard the health of workers in the use of lead paint, which remained the best mixture for paints.

Dr. Hastings, in supporting the Bill, said that in addition to the deaths among house painters a vast amount of ill-health was caused. The chronic absorption of lead increased their susceptibility to other diseases, but the most serious result was the terrible effect on their children.

Dr. Chapple also supported the Bill.

Mr. Henderson, Home Secretary, said that the Government could not go forward with the regulations unless the second reading of this Bill was agreed to. He understood that the fight was in regard to whether Clause 1 (Prohibition) should be deleted. If the House was prepared to give the Government the second reading of the Bill, he was prepared to do the fighting in Committee. If Clause 1 were deleted he would still proceed with the remainder of the Bill.

After further discussion Mr. Harney's amendment was withdrawn, and the Bill was read a second time.

Housing Construction in Scotland.

Replying to a series of questions by Captain Elliot, Mr. W. Adamson, Secretary for Scotland, said the number of houses under construction in Scotland at May 31st, 1924, by local authorities under the 1919 Act was 2716; under the 1923 Act, 1380; and under slum clearance schemes, 1351. The number of houses for which schemes had been approved under these heads, but on which work had not been commenced was: 1919 Act, 628; 1923 Act, 5732; and slum clearance schemes, 4454. The number of houses under construction in Scotland at May 31st, 1924, by private enterprise under the Housing, &c., Act, 1923, was 2039. The number of houses for which approval of plans had been granted but on which work had not then been commenced was 1474. The number of houses under construction in Scotland at May 31st, 1924, under the Housing, Town Planning, &c. (Scotland) Act, 1919, was 2841; the number for which tenders had been accepted though work had not then been commenced was 482, and the number still to be tendered for was 146. The extension of time given for the erection of houses under the Housing, Town Planning, &c. (Scotland) Act, 1919, expires on August 19th, 1924. It is estimated that a further extension of time will be required for about 2000 houses, but it is not possible at present to fix a definite date by which these will be completed.

Tuesday, June 24th.

Bacteriological Examination of Specimens.

Mr. Black asked the Minister of Health whether, in the interests of the health of the community, he would arrange to give a grant of 50 per cent. on the net cost of bacteriological examinations of specimens forwarded by medical practitioners to the medical officers of local authorities, with an arrangement with the authorities that the cost should be recovered in cases where the patients were able to pay.—Mr. Greenwood (Parliamentary Secretary to the Ministry of Health) replied: Medical practitioners can generally obtain from local authorities reports on bacteriological examinations of specimens forwarded in cases where the diagnosis of venereal disease, tuberculosis, or acute infectious diseases is in question. The expense of such examination is in most cases defrayed by the local authorities. My right hon. friend will be prepared when time admits to consider the arguments for or against an extension of the existing facilities.

Appointments.

Park, W., M.B., Ch.B. Edin., has been appointed an additional Medical Referee under the Workmen's Compensation Act for the County of Orkney.

Certifying Surgeons under the Factory and Workshop Acts: **Hyatt, A. W.**, M.B., B.S. Lond. (Shepton Mallet); **Laing, A. C.**, M.B., Ch.B. Edin. (Levenwick).

Vacancies.

For further information refer to the advertisement columns.

Birmingham City Anti-Tuberculosis Scheme.—Asst. Res. M.O. £450.

Blackburn and East Lancashire Royal Infirmary.—Third H.S. £200.

Blackburn, Calderstones, Whalley.—Asst. M.O. £440 16*s.* 11*d.*

Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—P. 100 guineas.

Bradford City.—M.O. £600.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

Coventry and Warwickshire Hospital.—Jun. H.S. £130.

Delhi, Lady Hardinge Medical College.—Lecturer in Physiology. Rs.750 p.m.

Derbyshire Education Committee.—School M.O. £600.

Durham, Richard Murray Hospital, Blackhill.—R.M.O. £400.

Gilbert and Ellice Islands Colony.—Sen. M.O. £650.

Gloucestershire Royal Infirmary, Gloucester.—P.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Gynæcologist.

Hong-Kong University, Faculty of Medicine.—Professor of Obstetrics and Gynæcology. £800.

Hospital for Consumption and Diseases of Chest, Brompton.—R.M.O. and Reg. £500. Also H.P. £50.

Leamington Spa, Warneford, Leamington, &c., General Hospital.—Res. H.P. £150.

Leeds Public Dispensary, North-street.—Jun. R.M.O. £150.

Lincoln, Bracebridge Mental Hospital, nr. Lincoln.—Sen. A.M.O. £350.

Liverpool, Samaritan Hospital for Women.—Hon. Asst. S.

London Temperance Hospital, Hampstead-road, N.W.—H.P. £120.

Manchester Royal Infirmary.—Second Surg. Reg. £150.

Melbourne University, Victoria, Australia.—Chair of Pathology. £1200.

Middlesex Hospital, W.—R.M.O. £250.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. £100.

Northampton General Hospital.—Sec. Supt. £400.

Royal Chest Hospital, City-road, E.C.—P. to Out-patients.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W. Reg. and Clin. Asst. 100 guineas.

St. Bartholomew's Hospital.—Asst. P.

St. Bartholomew's Hospital Medical College.—Demonstrator of Physiology.

St. Thomas's Hospital.—Visiting Anæsth.

South London Hospital for Women.—Clinical Asst. (Ophthalmic) to Out-patients.

University College Hospital, Gower-street, W.C.—Asst. to Venereal Dis. Dept. £250.

University of London.—External Examiners.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Each £100. Also Ophth. S.

West London Hospital, Hammersmith-road, W.—Asst. Anæsth.

Wolverhampton and Staffordshire Hospital.—H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

Brierley.—On June 16th, at Dunera, Richmond-avenue, Bognor, the wife of Lieut.-Colonel C. I. Brierley, I.M.S., of a son.

Driver.—On June 20th, at Victoria-square, Clifton, the wife of H. Lloyd Driver, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

Fenton.—On June 23rd, at Devonshire-street, W., the wife of Victor N. Fenton, M.A., M.B., B.Ch. Camb., of a son.

MacMurray.—On June 9th, at Windsor-crescent, Newcastle-on-Tyne, to Lilla, wife of Dr. W. MacMurray, M.D., Ch.B., of a daughter.

Richards.—On June 23rd, at 21, Endsleigh-street, to W. A. Richards, M.B., B.S. Lond., and the Hon. Mrs. Olivier Richards, M.D., M.R.C.P.—a son.

DEATHS.

Connolly.—On June 20th, at Kingsclere, Harrington-road, Brighton, Colonel B. B. Connolly, C.B., late Asst. Director of Medical Services.

Davies.—On June 16th, at Parkwern, Frome, William Henry Davies, L.R.C.P. Lond., M.R.C.S., J.P., in his 80th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, July 2nd.

ANNUAL GENERAL MEETING OF FELLOWS: at 5 P.M.

Thursday, July 3rd.

OBSTETRICS AND GYNÆCOLOGY: at 6 P.M.

Prof. Stroganoff (Leningrad) will open a discussion on his "Treatment of Eclampsia."

Saturday, July 5th.

ELECTRO-THERAPEUTICS: Conjoint Meeting with the Rontgen Society at the Radcliffe Infirmary, Oxford.

Mackenzie-Davidson Memorial Lecture at 3.30 P.M.

Sir Thomas Horder: The Influence of Radiology upon the Criteria of Disease.

Paper: at 5 P.M.

Prof. Sidney Russ: Experimental Studies upon the Lethal Doses of X Rays and Radium for Animal Tumours.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, July 3rd.—5 P.M., Mr. Richard Lake: Intra-Cranial Complications of Middle-Ear Diseases. (Geoffrey E. Duveen Lectures in Otology.)

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, June 30th.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—11 A.M., Dr. Archer: Chemical Pathology. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

WEST END HOSPITAL FOR NERVOUS DISEASES. (At the Royal Society of Medicine.)

THURSDAY, July 3rd.—5 P.M., Dr. Arthur Hurst: The Savill (Memorial) Lecture

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-street, W.C.

THURSDAY, July 3rd.—4 P.M., Mr. Fairbank: Hip Disease.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

TUESDAY, July 1st.—5 P.M., Dr. MacLeod: Leprosy.

THURSDAY.—5 P.M., Dr. Barber: Tuberculosis.

TRAINING COLONIES AND VILLAGE SETTLEMENTS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.[*]

BY JOHN B. MCDOUGALL, M.D. GLASG.,
M.R.C.P. EDIN., F.R.F.P.S. GLASG.,
MEDICAL SUPERINTENDENT, WOOLEY SANATORIUM, HEXHAM, NORTHUMBERLAND.

THE subject of my address has at least one thing in its favour. It is neither a purely administrative problem nor yet is it entirely clinical; at the same time, it merits consideration from both branches of the tuberculosis service, if those two distinct branches actually do exist.

The Training Colony of To-Day.

The training colony of to-day has, as its special work, the training of tuberculous patients—usually ex-Service men—in some particular occupation. At the end of a certain time, which varies in different places and with different cases, these men receive (or do not receive) a certificate of health and industry which is, from the purely administrative standpoint, supposed to be the passport to prosperity in life generally. In nine cases out of ten the training colony takes no further interest in the future of the ex-trainee. The statistics given by Bardswell show that it is only very rarely possible for a man on the completion of his training to find a situation in the outside market in the trade in which he has been taught. The man's physical condition may be excellent, but the entire work which the training colony has set out to do, and which to a certain extent it does very well, breaks down at the most crucial point because the training colony scheme per se has made no arrangement for the future of the man. He is expected, as a solitary individual, to go out and fight his own industrial battle. He is expected to find a job, or be dependent on someone, or upon some half-hearted organisation—e.g., a labour exchange—to provide him with work. Alternatively he is supposed to set up a business of his own, often with little or no capital, and against much local prejudice in many cases.

A recent circular from the Ministry of Health has been published, urging that at least six weeks' notice should be given to the tuberculosis officer of the impending discharge of a patient so that reasonable efforts may be made to find employment for those who are discharged from sanatoriums. The intentions are excellent, but I doubt whether any real help to the ex-trainee will result.

The After-Care Committee.

I do not believe that any but a few of our present after-care organisations will assist much in the economic salvation of discharged sanatorium and colony patients. There is far too great a tendency at present to regard after-care committees as charitable organisations, instituted for the purpose of bestowing temporary relief. This is, no doubt, quite a legitimate object, and one which may even justify the existence of after-care committees, but I contend that they are of very limited value in assisting in the real economic solution of the patient's future. Some of us have had the temerity in the past to speak and write on the functions of an after-care committee and to enumerate an imposing array of occupations suitable for the ex-patient.

The plight of an after-care committee, when presented with a case such as the following, may be well imagined. A patient who has just completed a course of instruction as a cabinet-maker in a training colony is referred by the tuberculosis officer to the after-care committee for "suitable employment." This body, composed of laymen and laywomen, is not, as a rule, adept at finding suitable jobs for discharged patients. The members may know of a few windows to be cleaned or of a lawn which is to be mowed, but to face the problem of finding anything like permanent employment for men already skilled in an occupation is a task too often beyond them. And can we wonder at their special difficulty when consulted by an ex-trainee? The man, whilst working at the training colony, was working as one in a unit; after his discharge he *is* the unit himself. It required a large amount of capital expenditure to establish training colonies throughout the country; to expect the ex-trainee to build up a "colony" of his own without capital seems a paradox.

I am far from ridiculing the work of after-care committees. I believe they have a definite function to fulfil. They can, as charitable organisations, bestow charity which is most certainly needed in many cases ; they can organise, according to the abilities of the various members, a disorganised home and can befriend and show kindness in innumerable ways to sufferers themselves. But they cannot solve the real economic factor in the after-care of the tuberculous individual —his permanent employment in industry. Their knowledge of local industrial conditions may be good, often it is not ; their anxiety to help may be overwhelming, but their efforts are in turn overwhelmed by hosts of factors over which they have no control, such as scarcity of employment in a district, prejudice towards the ex-patient on the part of employers and employees, and, most important perhaps of all, the lack of the 100 per cent. vitality in the person whom they are most anxious to help. It may, indeed, be easier for an after-care committee to place an ex-patient who is *not* a trainee, than to find employment for an ex-patient who is a trainee. The time has come for us to realise that what I have termed the "economic salvation" of our patients is something quite beyond the resources of our existing machinery. And yet there is not one amongst us but is certain that if the majority of our middle-stage cases especially were given a real chance of making good whilst working for a reasonable wage at a suitable job in ideal hygienic surroundings, then we should go far towards our goal.

---

[*] An abstract of an address delivered to the Yorkshire Tuberculosis Society.

How, then, is the difficulty to be met ? Obviously not by returning the ex-trainee, unassisted in any way, to his previous home and surroundings, even although reinforced to a certain extent in health and with the knowledge of a new occupation. Some have even condemned this procedure as a betrayal, for there is not the slightest doubt that many patients have in the past taken up occupational therapy on the distinct assumption that their after-care was assured. It is now nearly four years since the Ministry of Health, together with the Ministry of Pensions, agreed to institute the scheme of training colonies at different centres throughout the country. At that time I had the honour to be in the service of the West Riding County Council, one of the local authorities concerned, and in response to a request by the tuberculosis subcommittee I made a report, in which I emphasised the fact that the county council ought not to proceed with the training colony unless they were at the same time prepared to formulate measures for the future employment of the discharged trainee. The report was approved and agreed upon ; the training colony was opened, but before many trainees had completed their course of instruction, it became more and more evident that it was essential for the after-care part of the scheme to proceed. It did not, and now, nearly 40 months after the initial warning, I am informed that the policy agreed upon four years ago is to be adopted in a modified form.

Since coming to Northumberland I have had ample opportunity of studying the question from an even more practical standpoint, and feel more certain than ever that the policy of establishing training colonies as such, without sincere and business-like thought being given at the same time to the future of the trainee, is a bad policy. I believe it is a step in the right direction, but I hold that no local authority should be permitted to begin training colonies without some guarantee that their vision goes beyond mere workshops, and the installation of machinery and instructors in the grounds of the sanatorium.

Already training colonies are largely in disrepute, even amongst tuberculosis officers and medical superintendents, who adopt the term "blind-alley" to describe the end-results of occupational therapy as conducted in the majority of training colonies. Many feel that they are following in the wake of other anti-tuberculosis measures, not because they are wrong in principle, but because they are lacking in finality.

Difficulty of Finding Occupation for the Tuberculous.

It is, I suppose, a generally accepted axiom that it is necessary for a large percentage of middle-stage cases of pulmonary tuberculosis to continue to spend the remainder of their lives in ideal hygienic surroundings, and for this it will be necessary, also, for them to change their occupations. A few may be already in the fortunate position that their ordinary occupation can be carried on without loss in money or in health, but this is very much the exception—in the North of England at any rate. In the great majority of instances the patient must be given fresh knowledge. The middle-stage case of tuberculosis in a miner is one where it would be difficult even under the most ideal surroundings to advise a return to underground work. Employment on the surface would at best be only a temporary affair, with the risk of relapse very great. Besides, there is a "brisk demand" for work on the "top." What is one to advise in such a case ? I see no hope whatever unless a new occupation is given to him, taught thoroughly, and selected only after one gets to know the mind of the patient as well as the physical signs in his chest. At the same time it is, in my opinion, essential that before he undertakes the period of training he should be given definitely to understand that the object in training him is to make him a member of a settlement in which he can go on working for a reasonable wage. To enable this guarantee to be given, we must invoke the aid of the settlement, and it is my special plea to ask you to press for settlements of some kind in connexion with the treatment of pulmonary tuberculosis.

The Establishment of a Settlement.

There is a great variety of settlements to choose from, but all have one thing in common—they are extremely difficult to begin. It is, in fact, at this special point that the whole programme for the "complete solution of the problem" as outlined by us doctors breaks down. The link between the training colony and the settlement is by far the most difficult to join up, for the simple reason that the establishment of a settlement is not a medical problem at all. Training colonies were given to us as an adjunct to treatment, and medical superintendents have courageously faced their charge, but settlements were not given to us ; they were the ideal which was to evolve somehow or other from the training colonies. To expect a medical man to be an expert physician, an administrator of ability, and at the same time a business man, fully equipped with a knowledge of industrial markets, is, I submit, asking too much of the majority of our profession. With sanatorium work proper, clinical and administrative, there can be no dispute as to who should be the responsible person, nor should the medical superintendent be freed from taking an active interest in the administrative side of the training colony, more particularly in so far as these problems affect the administration of the sanatorium itself.

The essential thing for the establishment of a settlement is for the training colony, from which the settlers will come, to be eventually in a position to produce material for which there is a certain market. Granted a market for the products of the colony it will be hard enough to make the settlement self-supporting, but if there is only a precarious market or none at all, then the future of any settlement is doomed from the beginning. No amount of financial assistance from Government or any other source can justify the continuation of a scheme which requires large and constantly recurring capital expenditure, maintenance, and wages, and yet which is running at a dead loss. It is for this reason that I emphasise now the very great importance of choosing the most suitable occupations to be taught in the colonies. And as this duty will almost certainly fall on the medical superintendent of the sanatorium, I feel that too much consideration cannot be given to this matter. I go further and say that it is infinitely better for the future of the settlement to have one trade taught in the colony, a trade which can be carried out efficiently and for the products of which there is a constant demand, than to have a multiplicity of instructors teaching handicrafts which, however exquisite the products may appear to the eye, have little or no value as a sound commercial or business proposition. This is, after all, only common-sense business logic, but it is the kind of logic which is being pursued in quite a minority of the training colonies in this country to-day. It is, no doubt, entertaining to see a display of fancy jewellery made by consumptives, but I should not feel convinced that the manufacture of fancy jewellery was a good thing to teach trainees unless I felt certain that the products would one day enable ex-trainees to come into residence as settlers, and make their wages from the profits on their sale. One could mention at least three training colonies which are running at a loss. In two of these four different occupations are being taught. There is one training colony where the loss amounts to as much as 8*s*. per patient per week. Now, if training colonies, with comparatively low overhead charges, cannot be made to run at a profit, how is it going to be possible to inaugurate settlements where the financial outlay in wages alone must be large if the settlement is to be of any real value in the treatment of tuberculosis ?

Perhaps those of us who are engaged more or less constantly in dispensary work, and therefore see little of the colony and settlement aspect of treatment, will ask, "But is it possible to make profits out of any scheme in which tuberculous men are the workers ?" Most decidedly it is. I believe I am right in saying that there is one institution in England where the turnover is no less than £1000 per month in one single branch of its activities, and the profits are sufficient to pay trade-union wages to over 20 men. Another very progressive scheme for the benefit of tuberculous ex-Service men is about to undertake a contract under a local authority for £30,000. At the sanatorium to which I have the honour to be attached we have succeeded in the comparatively short period of eight months in making profits from an industry, for the products of which there is a keen and ready market, sufficient to pay a reasonable wage and maintenance for one year to three men. I see no reason, granted the necessary sum of money is forthcoming for capital expenditure, why the same industry should not be made the medium of support for 30 men.

Importance of the Business Side.

Most certainly there are great openings for special industries in special places, but it is unfair to expect medical men, even if they have started a venture of this kind, to be saddled with the responsibility of developing what I conceive to be a purely business affair. Nor do I wish to convey to you the impression that the medical superintendent should take no interest whatsoever in the settlement. If he has none, then you may be sure his committee will have none. His function should be rather to bring together the members of his committee who are, with him, interested, and whom he knows to be men of recognised business ability. The business side of the concern leading up to the establishment of the settlement ought to be left in the hands of business men. Few sincere business men on the various committees will shirk this responsibility, especially if they see that there is a prospect of helping the cause of public health at the same time.

A Successful Settlement.

One settlement in a country such as ours is, of course, useless. Dr. Varrier-Jones's personal contribution to the diminution in the mortality-rate from consumption is infinitesimal, but if his example were followed by 1000 others the net result would be something very appreciable. I have said previously that there can be a great variety of settlements. The well-known one at Papworth is one very distinguished variety, but it is quite wrong to assume that for a settlement to exist at all it must necessarily be a replica of that very excellent institution. In its very beginnings the Papworth Settlement was a miniature affair; it has developed strictly in accordance with the business capabilities of those responsible for its administration. A settlement where men and their wives and families live together in beautiful and well-appointed modern cottages with every possible convenience is just about the last thing to be considered in the *establishment* of a settlement. There is, however, no harm done in keeping this Utopia well in mind, although the picture has been rather over-emphasised to the absolute neglect of the principle that it is of greater consequence to guarantee the continued existence of such cottages when they are built, and if possible to justify the expenditure of fresh capital in building others. Personally, I am of the opinion that ordinary huts, where men can live as in the training colonies at present in existence, suffice for the preliminary stages of any settlement scheme. It has, I know, been said that isolation from friends and relatives, and the absence of "town life" are insuperable obstacles, but I do not believe that the middle-stage case of tubercle—the man who has been ailing for some years and who has attempted his previous occupation and failed repeatedly—will allow sentiment to interfere with a reasonable chance of keeping alive in good atmospheric conditions and of earning a living wage. Trainees and settlers have a right to know what the future holds out for them, and my experience is that few of them will criticise the doctrine that profits go in wages, and that as soon as the venture justifies its existence *as a commercial proposition*, then cottages of the ideal type will be built, but not till then.

The Papworth scheme has proved itself to be sound; the health statistics are well known, but what is of even greater import from the point of view of the future of all settlements is that it is economically and financially sound for the Government and other bodies to sanction capital expenditure for the erection of additional buildings in which the amount of work turned out can be increased, and in which more men and their families can live. To analyse the success of the Papworth Settlement necessarily implicates the esteemed medical superintendent of the institution, whose very special business qualifications, apart from his outstanding abilities as a clinician, have been instrumental in placing Papworth Settlement in a position of "splendid isolation." I do refuse to believe, however, that we have doubly qualified tuberculosis officers capable of undertaking work of this kind in all the places in the country in which settlements are required.

I am pleading now for the more active coöperation of a new element in the completion of our schemes for the residential treatment of pulmonary tuberculosis. I would go so far as to say that a business committee, having as its function the development of the industrial side of a training colony and settlement scheme, would be a godsend to every sanatorium in this country. And if I am charged with attempting to introduce yet another link in the already complex chain, I will defend myself by urging that the after-care of the sanatorium patient is a problem of the first magnitude.

COLONIAL HEALTH REPORTS.

UNFEDERATED MALAY STATES.

Johore.—A census taken in 1921 shows that the population was 282,234. The number of births registered in 1922 was 10,223, and of deaths 8248. The territory has been again free from both plague and cholera. There were 23 cases of cerebro-spinal meningitis, of which 20 were fatal. 16 cases of chicken-pox and 32 of measles were reported; there were no deaths from either disease. Influenza was more prevalent than in 1921, 72 deaths being reported. There were 87 cases of small-pox with 6 deaths. Six cases of typhoid fever were reported, of which 4 were fatal. Excellent results have been obtained in the treatment of ankylostomiasis. In 1922 the cases were 1276 and the deaths only 46, compared with 1409 and 80 respectively in 1921. The number of deaths from beri-beri fell from 338 to 318, but the cases treated in the Government hospitals rose from 246 to 396, and it is feared that the improvement in the incidence of this disease, which was very marked during the period of food control, is being gradually lost. Only 7 cases of blackwater fever with one death occurred during the year. The cases of dysentery and diarrhœa numbered 728 with 141 deaths. Great improvement is shown in the figures for malarial fever. Not only have the total number of deaths been less (3821 in 1922 against 4719 in 1921), but the percentage of deaths to total cases treated in the hospitals has fallen from 8·81 per cent. in 1921 to 5·33 per cent. in 1922. Phthisis is unfortunately rapidly increasing both in its incidence and mortality. In the Government hospitals there were 408 cases and 192 deaths, against 247 cases and 140 deaths in 1921. The number of lepers in the Johore Leper Asylum at the end of 1922 was 45. Experiments were made on a few cases with the "Moorgol" treatment, but the results were, on the whole, disappointing.

Kelantan.—Dr. H. W. Furnivall acted as residency surgeon till Oct. 21st, when he was relieved by Dr. J. R. McVail. Dr. Lim Shin Thwin assisted in Kota Bharu when required, and Dr. W. J. Geale assisted in Ula Kelantan. Cholera broke out in April, 1922. There were 27 cases with 14 deaths, and 135 cases of choleraic diarrhœa with 75 deaths. There were 100 cases of influenza with 6 deaths. There were 2 cases of small-pox and 14 of chicken-pox; 6 deaths from pneumonia occurred in the State hospital and 16 in estate hospitals. The population of Kelantan continues to be highly infected with whip-worm, ankylostomiasis, and ascaris lumbricoides. There were 6 lepers in the leper camp at Kota Bharu on Jan. 1st, 1922, and 8 admissions during the year; 3 were discharged after treatment apparently cured.

Trengannu.—The health of the State in 1922 was fairly good; there is a notable absence of malaria except in up-country areas. The chief maladies were dysentery, venereal, worms, influenza, ulcers, yaws, and skin diseases of various kinds. Infant mortality was heavy among untreated cases and continues so in the Kampongs. Mr. N. Kington (a Chinese practitioner) was in charge of the medical department until October, when he was succeeded by Dr. A. B. Jesser Coope, seconded from the Straits Settlements. Mr. Kington did much good work under difficult conditions. Dr. Coope is the first European medical officer to enter Trengannu service. Provision has been made for the erection of a hospital and a suitable site has been secured. Medicines were supplied free of charge at the Government dispensary throughout the year; this privilege is liable to abuse, and it is doubtful whether medicines obtained without cost are properly valued.

Kedah.—The population is estimated at 340,000. The birth-rate in 1922 was 30·30 and the death-rate 25·40 per mille. There was a marked improvement in infantile mortality, the rate being 165·36 as against 194·98 in the previous year. The number of deaths in the State was 8656, of which 4378 were attributed to fever, but the returns are not very reliable. The only accurate figures are those from the hospitals. Eight Government hospitals were maintained and 13,018 patients treated therein. The principal diseases were malaria, venereal diseases, ankylostomiasis, dysentery, pulmonary tuberculosis, and pneumonia. In addition to the out-door departments at the hospitals there are 7 Government dispensaries in the State; they did good work, the number of prescriptions dispensed being 25,025. Kedah was free from any epidemic or infectious disease, but sporadic cases of small-pox occurred throughout the year; there was a total of 15 cases with 4 deaths; 22,566 people were vaccinated. Nearly 3000 persons, almost all of whom were Malays, were injected with neosalvarsan for paru (yaws); the immediate results were wonderfully good. There was a considerable increase in the number of deaths due to diseases connected with childbirth. The prejudice against competent medical assistance in such cases remains very strong, but it is hoped that the proper training of Malay midwives may lead to better results. There remained 50 lunatics from Kedah under treatment at Tanjong Rambutan at the beginning of the year; 40 more were sent, 11 were discharged, 7 died, and 5 absconded. 31 lepers were being maintained by the State at Pulau Jerejak and 6 at Pulau Pangkor Laut, The accommodation at these places is limited, and 11 patients were awaiting vacancies at the end of the year. A separate health department was started at the beginning of 1922, Dr. A. G. H. Smart being appointed health officer.

Perlis.—There were 613 births registered in 1922, these comprising 518 Malays, 29 Siamese, 62 Chinese, 3 Tamils, and 1 Bengali. 606 deaths were registered—viz., Malays 479, Siamese 25, Chinese 85, Tamils 15, Bengali 1, and 1 of other nationality. The number of in-patients treated in Kangar Hospital during the year was 519, including 25 females. The number of out-patients was 9269 as against 7425. Malay admissions increased from 48 to 67. The prevalent ailments are venereal disease, malaria, and ulcers. Diets were provided by departmental catering, ordinary diets at 19 cents, and milk diets at 28 cents. Three lepers were admitted during the year and transferred to Pulau Jerejak, making a total of 5 maintained there by Perlis. One case of infectious disease (small-pox) occurred in Kangar; precautions were immediately taken and there were no further cases. An isolated case of chicken-pox was treated in the hospital, and several mild cases of measles were reported from the Kampongs. The total number of vaccinations performed during the year was 1815, of which 1613 were successful.

WOMEN'S HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—May we ask you again this year to allow us to appeal on behalf of the Women's Holiday Fund? A holiday to many of the women living in the poorer districts of London is an impossibility, for it cannot be paid for out of the weekly money earned. Among the 200 applications already received this year, 20 applicants have never had a holiday throughout their lives, 18 have not had one for over ten years, and 28 not for more than four years. The approximate cost of a fortnight's holiday is £3 or £3 10*s.* for a mother with a baby, towards which the women contribute on an average less than one-third.

Surely, it is not an impossible thing to hope that among the many thousands who enjoy a holiday every year there may be at least 1000 who would like to give the sum of £2 to our Fund, and thereby help to send back refreshed and cheered, after a fortnight at the seaside, one of the many wives and mothers on whom the happiness and well-being of our homes largely depends.

Donations should be sent to the Secretary, Women's Holiday Fund, 76, Denison House, 296, Vauxhall Bridge-road, S.W. 1.—We are, Sir, yours faithfully,

A. F. LONDON.
MANUEL J. BIDWELL, Bishop of Miletopolis.
J. SCOTT LIDGETT.
HELEN A. POWNALL,
Chairman of the Executive Committee.

"THE SCOURS."

To the Editor of THE LANCET.

SIR,—An extremely interesting experiment has been carried out by me at my farm at Southwood, Westerham Hill, Kent, with a view to finding out the cause of enormous losses amongst pig-breeders during the months of March, April, and May from so-called "scours." By "scours" the ordinary farmer means that his pigs have a peculiar kind of diarrhœa, usually yellowish or white in colour, sometimes a little mucus, hardly any, if any, blood. The disease is acute, and death takes place within 48 hours. The post-mortem results show nothing more than a general inflammatory condition of the stomach and the whole of the mucous membrane lining the intestine. The mucous membrane is œdematous and very red. There is no ulceration on macroscopic examination. The pigs become rapidly weak and from being a perfectly normal pig 48 hours previously, it now becomes tottering and so weak that it is unable to take food, even to suckle its mother. This condition generally arises in pigs of about 3 to 4 weeks old.

Cultures were taken by me from the stools of pigs suffering from this symptom and from those not affected, and no difference could be found in any of the organisms. It has often been stated that this condition is due to lack of mineral salts, chiefly calcium; by others it has been stated to be due to lack of iron. Several of the pens suffering from so-called "scours" were treated by the addition of powdered chalk and powdered calcium with phosphates and hæmoglobin, yet the results were disastrous. I was so convinced that the condition was one due to deficiency of vitamin A that I added quantities of dried yeast to two lots, and to another two lots I added a sufficient quantity of a proved food rich in vitamin A, and within 24 hours those to which had been added food containing vitamin A were almost well, whereas those to which vitamin A had not been added to their food were rapidly dying. To these was given a mixture containing cod-liver oil which had been tested by me for its vitamin-A content and they immediately recovered, even those that had been at death's door.

It is interesting to note the months of the year when this disease is prevalent—namely, March, April, and May. One would have expected this condition to have occurred during the hot summer months or during the winter months when the weather is bad and the piglets are exposed to adverse weather conditions. The reason is now easily explained: that those piglets which are born during the summer months are from sows that were grass-fed during the spring, and thus the milk of the dam is rich in its vitamin-A content. I am well aware of the value of mineral salts to growing animals, yet my experiments definitely prove that mineral salts are of but little value in the absence of vitamin A. I was surprised to find, contrary to most experimentalists, that the cabbage family, the *Cruciferæ*, are deficient in vitamin A. Now this opens up a most important point to us as medical men—that milk from cattle which are fed on concentrated cake foods are deficient in vitamin A, as I carried out an experiment in feeding pigs on the usual diet given to dairy cows, and their offspring suffered from diarrhœa. Immediately the piglets were given cod-liver oil the diarrhœa stopped. Also several of these pigs on post-mortem examination were found to have small pneumonic areas of consolidation, undoubtedly due to lowered resistance owing to the deficiency diet.

I am, Sir, yours faithfully,
Knightsbridge, S.W., June 23rd, 1924. M. J. ROWLANDS.

A MATTRESS FOR BEDRIDDEN CASES.

THE inadequacy of the ordinary hospital mattress in bedridden or incontinent patients is familiar to anyone who has been burdened with the care of patients of this type. Even with the most conscientious nursing care it is almost impossible to keep these patients clean and comfortable. Working in conjunction with Miss Anna Scanlan, R.N., of the Bellevue Training School, Dr. J. F. Montague[1] has devised a mattress which has been used with much satisfaction in several large hospitals and private homes in New York City. In size and general appearance the mattress devised resembles an ordinary single-bed mattress, and may be used on any bed or any spring. It differs, however, from the ordinary mattress in possessing a recess built into the centre of the mattress to accommodate an excretory receptacle (Fig. 1). This recess is filled by such receptacle and a mattress section or by two mattress sections as required; with the two sections in place the mattress may be used as an ordinary one (Fig. 2). When the receptacle is in use the recess, and the mattress for about one foot around, is covered with rubber cloth in case of accidental spilling of excreta, though this, with ordinary care, seldom occurs. The patient is made comfortable by lying on a rubber ring, cushion, or pneumatic horseshoe which is placed on the bed-pan or douche-pan. The latter has appeared preferable in many instances. To change the pan the patient is half turned and the outer section withdrawn, while the soiled pan is replaced by a clean one, and is then put back.

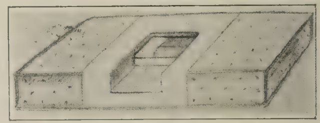

FIG. 1.—The mattress with bed-pan in place.

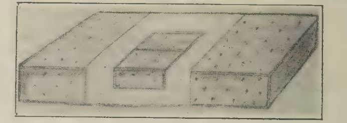

FIG. 2.—The mattress with the gap filled up.
From "Surgery, Gynecology, and Obstetrics."

In cases not incontinent this type of mattress, because of the depressed position of the pan, allows natural excretionary function without disturbance to the patient. This may be of prime importance in cases of pneumonia, apoplexy, or after recent abdominal section. The author suggests that the mattress can be utilised with advantage in procuring specimens in difficult cases, for giving enemas, for catheterisations, for giving high colonic irrigations, in obstetrical cases, and in those psychopathic cases that need continual restraint. It may also be of value where plaster casts are worn over a period of time.

The device seems to us to be of considerable merit. One point which the author has omitted to discuss is the arrangement of the sheet. Presumably separate sheets for the upper and lower part of the bed would be required, with a draw sheet to cover the central area.

Farbwerke vorm. Meister Lucius & Brüning, Hoechst a. M., Germany.

Alival "Hoechst"
Organic **Iodine Preparation.**

63% Iodine. For internal and external employment and for injection; well tolerated; lues, arterioscleros's, &c.

Original Packages.—Tubes of 10 or 20 tablets of grains 5 (0·3 gm.) each. Boxes of 5 or 10 ampuls of grains 15 (1·0 gm.) each.

Hexophan "Hoechst"
The extremely efficacious **Gout-Remedy.**

Well tolerated, dissolving uric acid, diuretic action. Internally: Thrice daily grains 15 (1·0 gm.). Subcutaneously: grains 15 (1·0 gm.) Hexophan-Lithium.

Original Packages.—Tablets of grains 15 (1·0 gm.); effervescent Hexophan-Lithium-Salt; (Original bottles) Hexophan-Lithium 25% solution (in ampuls).

NOVALGIN "Hoechst"
(Sodium Phenyldimethylpyrazolonmethylamidomethansulphonate)
Highly active **Antipyretic, Antirheumatic, Analgesic.**

PROPERTIES.—Quickly efficacious, easily soluble, nearly tasteless, well tolerated, may be injected without producing irritation of the tissue.

INDICATIONS.—Acute and chronic forms of Polyarthritis, muscular rheumatism and neuralgia, lumbago, sciatica, infectious fever; menstrual troubles; prophylactic against after-pains at operations.

DOSAGE.—Internal: 3-4 times daily, 1-2 tablets grains 7½ (0·5 gm.); as antipyretic also in shorter intervals (every hour grains 1½ (0·1 gm,) or every 2-3 hours grains 4 (0·25 gm.). **Parenteral:** 1-2 times daily 1-2 c.c. of the solution of 50% subcutaneously or intramuscularly.

ORIGINAL PACKAGES.—Novalgin Tablets: tubes containing 10 tablets of grains 7½ (0·5 gm.). Novalgin Solution 50% boxes containing 5 and 10 amp. × 1 c.c. = grains 7½ (0·5 gm.). Novalgin Solution 50% boxes containing 5 and 10 amp. × 2 c.c. = grains 15 (1·0 gm.).

Amphotropin "Hoechst"
An Internal **Urinary Antiseptic**

Bactericidal properties, diuretic action, accelerated regeneration of the sloughing epithelium. In cystitis, &c., thrice daily grains 7½ (0·5 gm.).

Original Packages.—Tubes containing 20 tablets of grains 7½ (0·5 gm.)

Alumnol "Hoechst"
Non-toxic **Antiseptic.**

Antiphlogistic, growth-retarding action. Purulent wounds, gonorrhœa, catarrhs.

Dosage. — For gargling: 0·25-1%; as antiseptic: 0.5-3%; in urology and dermatology: 1-20%.

Samples and Literature will be sent to Medical Men at any time on request through:

Telephone;
ROYAL 2335.

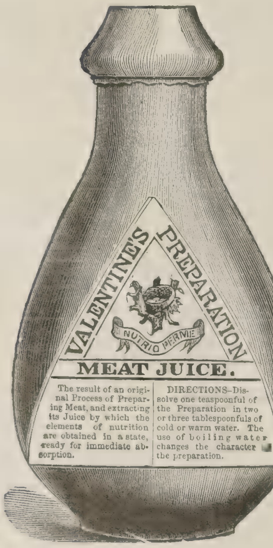
USE ALSO OUR HOLLAND STRAPPING. THE ORIGINAL AND STILL THE BEST.

LESLIES LTD., High Street, Walthamstow, LONDON, E.17.



The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.

DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

In Diarrhoea, Dysentery and Cholera Infantum where it is Essential to Conserve the Weakened Vital Forces without Irritating the Digestive Organs, Valentine's Meat-Juice demonstrates its Ease of Assimilation and Power to Sustain and Strengthen.

W. B. Scranton, M.D., *Medical Superintendent, Korean Mission Methodist Episcopal Church, Seoul, Korea*: "A most excellent use I frequently put VALENTINE'S MEAT-JUICE to is tiding Babies through Cholera Morbus and the Wasting Diseases incident to Summer and Inanition. It acts at once, and many a crisis has been passed safely by my patients, through the agency of VALENTINE'S MEAT-JUICE. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhoea known as Sprue, where it tides the patients over until they can get to a better climate."

F. E. Gordon, M.D., *Anniston, Alabama*: "My baby took VALENTINE'S MEAT-JUICE with relish and with great benefit, and to its sustaining properties I think her recovery from one of the worst cases of Entero-Colitis I ever saw was largely due."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
D 115 **RICHMOND, VIRGINIA, U. S. A.**

COAL MINERS' NYSTAGMUS

By FREDERICK ROBSON, M.D.

Price **10/6**; postage 6d. extra.

Copies may be obtained from the SECRETARY, THE SOUTH WALES INSTITUTE OF ENGINEERS, PARK PLACE, CARDIFF.

Dr. Robson's comprehensive and instructive paper, based on ten years' investigation while the author was engaged officially in South Wales and Monmouthshire, has now appeared in book form. In the author's opinion there appears to be one outstanding basic factor largely responsible for the genesis of nystagmus, and that is toxæmia or blood poisoning due to mine gases.

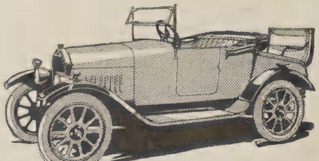
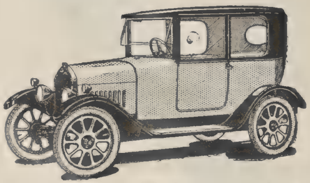
Humber

Models for Medical Men.

HUMBER OWNERS are continually writing to express their satisfaction with the road performance of their Cars. These letters verify and emphasize the popular view of the value of Humber models, and justify their selection. The little 8 h.p. Humber is in great demand and gives unqualified satisfaction :—



There are 3 different models on the 8 h.p. Chassis—a two-seater with comfortable dickey seat, a Chummy body, and a three-seater Saloon. The **Two-Seater** is remarkable for its grace of contour, comfort and utility, and like the Chummy body it is all-weather equipped. The **Saloon** created a great impression at the Olympia Show. Engine, chassis, and coachwork comprise all the outstanding features of Humber quality, and the upholstery is luxurious and comfortable.



"I have just completed a tour of 955 miles in North Wales in one of your 8 h.p. Cars. The Car has given me no trouble at all, and has run perfectly well throughout. Wherever I went the Car was admired, not only for the way it ran, but also for its finish and general appearance."—(Signed) A Weston-Super-Mare Doctor.

The 28 distinct types of

MR R. H. DENT'S

ARDENTE "ACOUSTIQUE"

TRADE MARK

FOR DEAF EARS

The advertisements of the "ACOUSTIQUE" aid to hearing which appear in the lay press insist upon the desirability of a personal fitting and invariably suggest a consultation in conjunction with the patient's own Medical Adviser.

The reason for this is obvious in view of the fact that there are no less than 28 distinct types of ARDENTE "ACOUSTIQUE," each of which is designed to give maximum assistance under a specific condition of deafness.

In determining the exact type indicated, the assistance of the Doctor is obviously invaluable, and Mr. DENT particularly requests that, where the personal attendance of the Doctor is inconvenient, the patient may be provided with a prescription.

To facilitate this arrangement, Mr. DENT will gladly send to any Doctor the fullest information of the various "ACOUSTIQUE" types and such further information as may be desired, or a practical demonstration of the "ACOUSTIQUE" will be arranged.

The ARDENTE "ACOUSTIQUE" is free from all trace of metallic sound—it is fitted with an exclusive NON-HEAD ATTACHMENT, rendering it practically invisible for both male and female wearer.

Of particular interest to the Profession is the ARDENTE "ACOUSTIQUE" STETHOSCOPE for deaf doctors, which is the ONLY thing of its kind and most efficient.

MORRIS
Cars

The Morris-Oxford Coupé has all the Qualities *essential* to a Doctor's needs. It gives him properly comfortable accommodation, with plenty of room for everything he carries with him on his rounds; it protects him from weather as efficiently as does his own Consulting-room; it enables him to make long rounds at all hours without fatigue, because it is extraordinarily *easy* to drive; it runs without a trace of vibration. He arrives at his patient's house untired, fresh, and with unruffled nerves and steady hands.

Active Permanent Elegant

ELIXIR COLLOID

A reliable and palatable preparation of the Thyroid Gland.

This elixir is standardised to contain 1 grain of the Colloid substance of the Thyroid Gland, equivalent to 7½ grains of Fresh substance, or 1½ grains of Dried Thyroid in each fluid drachm.

Indicated in Myxœdema and in congenital and surgical Athyroidism, in Psoriasis and Chronic Eczema.

It has been found beneficial in the treatment of certain forms of Obesity.

DOSE: 10–60 minims.

ELIXIR HYPOPHYSIS CEREB.

Each fluid drachm represents the active hormones of 3 grains of the whole Fresh Pituitary Gland, equivalent to ½ grain of the Dried substance.

Indicated in low Blood Pressure, Genital Dystrophy, delayed development and is beneficial in delayed convalescence.

Ameliorates the Hyperthyroidism of Pregnancy, Menstruation and the Menopause.

Administered with Elixir Colloid it greatly enhances the value of Thyroid in Obesity where the Basal Metabolic Rate is normal.

DOSE: 10–60 minims.

ELIXIR PARATHYROID

A preparation of Fresh Parathyroid Gland representing 1/10th grain of Dried substance or 6/10th grain Fresh Gland in each fluid drachm. Has a marked influence in Calcium Assimilation and Metabolism.

Also supplied in combination with Calcium Lactate as

ELIXIR PARATHYROID WITH CALCIUM

These Elixirs are indicated in Chronic Duodenal Ulcer, Sprue, Tetany, Chilblains, &c.

DOSE of the Plain Elixir 15–60 minims, and of the Elixir with Calcium 1–4 fluid drachms.

Intestinal Disinfection

No. 12.

ALLERGIC CONDITIONS AND PROTEIN SENSITISATION

Much attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (e.g., animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products), and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, &c.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases.

The best of all intestinal disinfectants is KEROL, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

KEROL CAPSULES

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

GOLD MEDAL, INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

MIST. DAMIANÆ CO. (HEWLETT'S)

MIST. DAMIANÆ CO. (**Hewlett's**) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps the principal reason is that multitudes have to toil harder with their brains than any previous race The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water.

MEDICAL OPINIONS.

"I have tried your Mist. Damianæ Co. considerably in the dyspepsia of commencing phthisis, and can very strongly recommend its use in those cases. **It soothes the stomach wonderfully, and enables the patient to take more food whilst acting as a powerful stimulant in relieving exhaustion.**"—Yours faithfully, W. H. B——, B.A. (Cantab.), M.R.C.S., L.S.A.

THE MEDICAL ANNUAL.—"Damianæ is not used so frequently in this country as in America, where its value as a tonic for Neurasthenia is well known. Messrs. HEWLETT & SON put up a very excellent preparation of this drug, combined with Nux Vomica and simple aromatics and bitters, which is valuable for dispensing, and yields very satisfactory results in treatment."—1898.

Dr. M——, R.N., writes:— Farnham (Hants.), Sept., 1903.
"I have frequently prescribed your Mist. Damianæ Co. and proved it efficient in treating Neurasthenia."

Packed in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Price in England 12/6 per lb.

Introduced and Prepared only by—

C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte Street, LONDON, E.C.2.

THE POTENCY AND INTEGRITY OF GLANDULAR EXTRACTS

The potency, integrity, and therapeutical value of glandular extracts and compounds depend upon the scientific equipment, skill, long experience, and knowledge of the suppliers, and upon the methods of preparation and standardisation employed by them.

These values equally depend upon THE FRESHNESS OF THE GLANDULAR EXTRACTS DISPENSED.

The disappointment resulting from the employment of more or less inert glandular products of doubtful origin, questionable freshness and inadequate dosage (now being widely offered to Practitioners), can be always avoided by specifying on every requisition and prescription " British Organotherapy."

British Medical Practitioners are invited to specify the Organotherapeutical products of this British House, and thus to ensure the supply of guaranteed preparations of maximum potency and of the highest grade obtainable, at all times.

PRESCRIPTIONS AND REQUISITIONS FOR ANY MONOGLANDULAR PRODUCT AND FOR ANY PLURIGLANDULAR COMPOUND ARE ALWAYS ACCURATELY DISPENSED FROM FRESHLY PREPARED GLANDULAR EXTRACTS (WITH OR WITHOUT PHARMACOPŒIAL ADJUVANTS), WITHOUT DELAY AND AT REASONABLE RATES.

ADVANCE IN TREATMENT
of
Hyperchlorhydria and Associated Conditions

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory. They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra-indicated, especially in stubborn cases.

"Alocol" does not neutralize acid; it absorbs the excess colloido-chemically and at the same time leaves a sufficiency for normal gastric digestion. The outstanding advantage of "Alocol" as an antacid is that it removes from the system the causative acid radicle (Cl), instead of merely temporarily neutralizing it. "Alocol" can be used for prolonged periods without the slightest harmful effect.

A supply for clinical trial with full descriptive literature sent free on request.

M.198.

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity. It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy, gastric and duodenal ulcer, gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis, flatulence, acid eructation and other symptoms common to gastric disease.

Fandorine

for

Menstrual Disorders.

Prepared at CHATELAIN'S LABORATORIES, PARIS.

Active Principles	*Indications*
Ovarian and mammary extracts. Anemone pulsatilla. Piscidia erythrina. Viburnum prunifolium.	Uterine hæmorrhage, Fibromas, Puberty, Irregular or painful menstruation, Menopause.

Fandorine is an association of the substances of the two essential types of the genital glands, to which are added the active principles of anemone, and constitutes a specific for all diseases peculiar to women. It *regulates the functions*, arrests hæmorrhage and suppresses painful symptoms.

Fandorine should be taken by any woman who suffers from irregularities or painful symptoms. It is highly recommended for young girls at the period of formation, as well as for women at the critical age.

Fandorine is also highly recommended during the period of pregnancy and nursing.

Necessary quantity for Clinical Trial obtainable post free from

INSULIN

"BOOTS."

Further Reduction in Price

Improvements in manufacturing methods enable us to make another striking reduction in the retail price of Insulin. On and after

JULY 1st, 1924,

INSULIN "BOOTS"

WILL BE SOLD AT THE FOLLOWING PRICES:—

PHIALS:—	5 cc.	(100 Units or 10 doses)	3/- each.
	10 cc.	(200 Units or 20 doses)	6/- each.

Ample supplies of INSULIN "BOOTS" are available. Every batch is made in Boots own Fine Chemical Laboratories, tested and standardised in their own Pharmacological and Bacteriological Laboratories, then before issue, is passed by the Medical Research Council for potency and sterility.

Research work on Insulin is still in progress, and as further improvements in method are discovered, the benefit will at once be passed on to the public.

When Metabolism is Faulty

OVALTINE

TONIC FOOD BEVERAGE

Easily Digested, Readily Assimilated, Palatable, Soluble, Highly Nutritive, Essential Food Elements in Correct Ratio. Reasonable in Cost.

The above are the distinguishing features of this delicious combination of ripe barley malt, creamy milk, fresh eggs and the purest cocoa. A complete food, that reinforces the diet in a way necessary to ensure successful treatment.

A deservedly popular prescription in the dietetic treatment of tuberculosis, chlorosis, gastric or duodenal ulcer, nervous disorders, infantile marasmus, and convalescence after fever or operation. In agalactia 'Ovaltine' is a definite galactagogue.

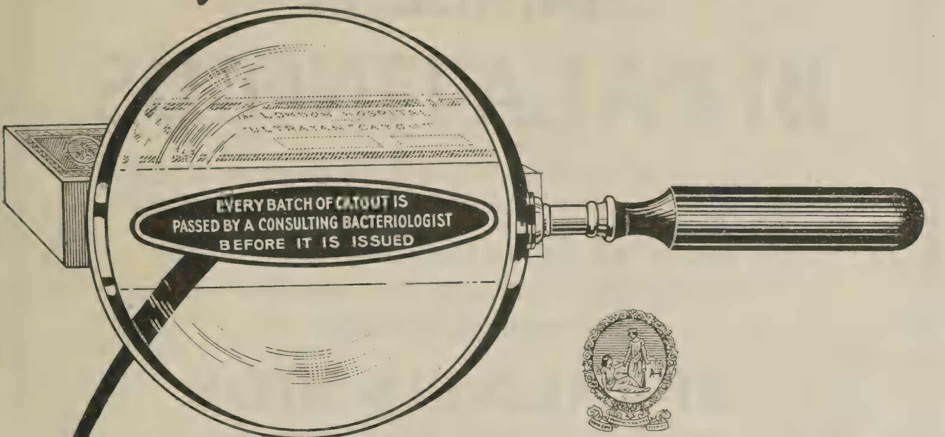
A. WANDER Ltd., 45, Cowcross Street, London, E.C. 1.

Works: King's Langley, Herts.

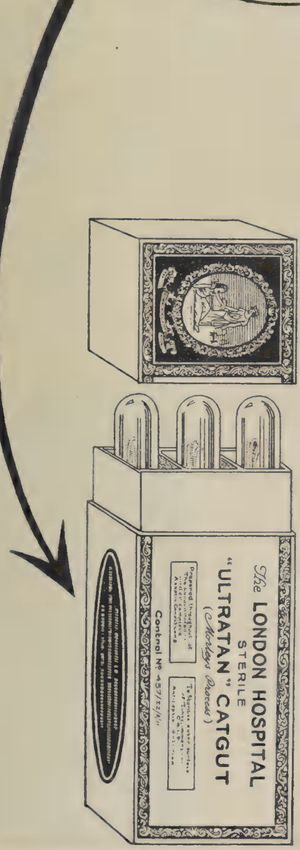
Drawing of a wall painting in a Theban Tomb, depicting Egyptian ladies at a feast.

A liberal supply of 'Ovaltine' sent free to medical men in private or hospital practice.

Dependable Sutures



EVERY BATCH OF CATGUT IS
PASSED BY A CONSULTING BACTERIOLOGIST
BEFORE IT IS ISSUED



LONDON HOSPITAL CATGUT

Each box of sterile "Ultratan" Catgut for surgical work bears a label stating that "every batch of catgut is passed by a consulting bacteriologist before it is issued."

"Ultratan" Catgut is prepared at the London Hospital, and is in continuous use in the 15 operating theatres there.

It is claimed for London Hospital Catgut:

1—Sterilisation commences immediately the intestine is split.
2—The tensile strength provides a wide margin of safety.
3—Every batch is passed by a consulting bacteriologist.

Descriptive booklet will be sent post free upon application to the sole distributors—

Allen & Hanburys Ltd.
48, WIGMORE ST., LONDON, W.1.

THE USE OF

BI-PALATINOIDS

in cases of acute anæmia and chlorosis is increasing rapidly—and rightly so, for the principle is one which by its simplicity and efficacy recommends itself to all members of the medical profession.

BI-PALATINOIDS

are gelatin capsules divided into two compartments, one containing the alkaline carbonate, and the other the sulphate of iron. On reaching the stomach, reaction takes place and NASCENT ferrous carbonate is formed which is AT ONCE dissolved in the acid gastric juice. Hence the very rapid progress made by the patient where Bi-Palatinoids are prescribed by the practitioner.

ESARHADDON, WHO CONQUERED LOWER EGYPT AND INCORPORATED IT WITH THE ASSYRIAN EMPIRE.—This king's claim to the title of empire-builder is well supported, for, in addition to holding intact what his predecessors had won, he extended the Assyrian power. His most outstanding achievement in this direction was the conquest of Lower Egypt in 672 B.C. Taking possession of the ancient capital of Memphis, he reorganised the administration of Egypt, making it part of the Assyrian Empire, though as a concession to his new subjects he appointed a native ruler. War continued to be the rule in Assyria during Esarhaddon's reign, notwithstanding that he reverted to the policy of conciliation of the Babylonians initiated by his famous grandfather Sargon. He began the restoration of Babylon, wiped out of existence by the iron hand of Sennacherib his father; he rebuilt its great walls and chief temple. He placed new images in its shrines, and led its people back from captivity. But Assyria and Babylonia never held together politically, and this was a serious element of weakness in the Assyrian empire, and ultimately one of the chief causes of its downfall. Esarhaddon conducted victorious campaigns against the Phœnicians and Cilicians, and subjugated encroaching tribes of Arabs and Medes. He seems to have been a somewhat less ferocious and ruthless ruler than most of his predecessors, an instance of this being his release of Manasseh, King of Judah, from the captivity which followed the repression of his revolt.

Peptonised Beef Jelly

(Benger) *An agreeable & highly-nourishing Invalid Delicacy.*

For those numerous cases in which solid nourishment cannot be safely prescribed, a palatable and nutritious food can be found in Benger's Peptonised Beef Jelly.

This preparation combines in an unusual degree the qualities of assimilability and high-nutritive content. It is superior to "Beef tea," as the meat itself is made soluble by the action of digestive enzymes.

The Jelly can be served either cold with biscuits, or dissolved in hot water as a soup-beverage. It is sold in hermetically sealed glass jars, ready for immediate use. Price **2**/- and **3**/- each.

Peptonised Chicken Jelly

(Benger) A pleasant change to the Beef Jelly is provided by Benger's Peptonised Chicken Jelly, made on the same principle and being similarly easy of preparation.

NOTE :—Benger's Beef Jelly and Chicken Jelly are entirely free from preservatives.

When Prescribing

tablets or pulverettes——

Medical practitioners have occasionally called attention to the fact that, in certain cases—e.g., where there is a deficiency of pancreatic enzyme—keratin-coated tablets or pulverettes are liable to pass undissolved throughout the intestinal tract.

For this reason, and at the suggestion of the correspondents referred to, sugar-coated Dimol pulverettes (B) have been prepared and are found to give greater satisfaction. They are partially dissolved in their passage through the stomach, but the action of Dimol is not impaired thereby, and is free to exert its powerful influence immediately after its passage through the pylorus ; whereas the keratin-coated pulverette (A), under the most favourable conditions, cannot be expected to get to work so quickly, and may, in fact, as above explained, pass undissolved.

The only possible objection to the sugar-coated tablet is found in the fact that on rare occasions it may cause slight eructation.

In prescribing, it will be necessary only to add the letter A or B, as may be indicated.

Dimol has been specially prepared for the Medical profession in the form of Pulverettes, Lavage Powder, Syrup, and Insufflation Powder.

Literature and Samples may be obtained from

In the Insulin Treatment of Diabetes the diet is still a factor of vital importance.

'Allenburys' Diabetic Flour

Is a special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is compact, convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

COMPOSITION:

	Per cent.
TOTAL PROTEINS	87·0
FAT	0·7
SODIUM BICARBONATE	1·6
ACID POTASSIUM TARTRATE	1·6
MOISTURE	9·1

Calorific Value—30·3 calories per 100 grammes
or 1,376 calories per lb.

A Doctor writes:

"I have tested the sample of 'Allenburys' Diabetic Flour which you recently sent me and find it makes admirable bread, etc.; it is both more easily digested and more palatable than any similar preparation I have come across."

Further particulars and clinical trial sample will be sent on request.

Doctor & Nurse Agree

that Baby's journey through life is best started with

Cow & Gate Milk Food

In two strengths: Full Cream, to enrich and maintain Mother's milk supply; Half Cream, for direct feeding for three months after birth.

Stringent tests by independent experts establish its outstanding merit. Infants develop bone and muscle naturally with COW AND GATE MILK FOOD, with no need for correctives or stimulants. Its ease of digestion is equal to natural feeding and relieves the parent from problems which otherwise recur.

Each tin carries full guidance for feeding infants from birth, children and adults. Prepared in England from the finest cows' milk; doubly sealed to ensure purity in all seasons. A complete, well-balanced food.

DEPT. I., COW & GATE HOUSE, GUILDFORD, SURREY

Trufood is a prophylactic against summer diarrhoea

	Breast Milk	*Cows' Milk*	*Humanised Trufood*
Lactose	6.5	4.7	6.25
Fat	3.3	3.5	3.45
Casein	0.9	3.0	0.80
Lactalbumen	0.4	0.3	0.60
Salts	0.2	0.8	0.65
Water	88.7	87.7	88.25
	100.0	100.0	100.0

The predominance of lactic organisms in the child's intestine is the surest safeguard against infantile enteritis in hot weather. In the intestine of the breast-fed baby Streptococcus Lacticus predominates over all other organisms. A similar condition is seen in the child fed on Humanised Trufood, but not when the basis of feeding is milk made by the roller process, etc.

In the Trufood process of manufacture, the maximum temperature reached never exceeds 145°F., so that lactic acid types persist in the finished product. In the older hot-drum process, in which milk is dried on super-heated cylinders at a temperature approaching 230°F., only spore-forming putrefactive organisms survive.

It would therefore be expected that if solutions of these two foods were incubated at blood heat, they would undergo very different types of fermentation. This is actually the case; milk made by the hot-drum process undergoes putrefactive change with marked proteolysis, whilst that made by the Trufood method shows typical lactic fermentation, evidenced by acid and curd formation. It is evident that the continued administration of either of these milks will tend to establish a corresponding condition in the alimentary tract of the subject.

Samples adequate for full clinical trial together with descriptive literature will be sent post free on request.

"Facts are stubborn things"

YOU HAVE A DUTY TO YOUR DEPENDENTS.

Protect them by effecting a life assurance with the

PRUDENTIAL ASSURANCE CO., LTD.,
HOLBORN BARS, LONDON, E.C. 1.

SAVE THE SMALL CHILDREN

A Practical Scheme for Focussing Public Attention.

The deaths of "toddlers" aged from one to five are far too many, in spite of the huge elimination in the first twelve months of life; and largely through the same preventable causes eight or nine out of ten children arrive at school age handicapped by avoidable physical defects.

To call public attention to this matter the *Daily News*, with the approval and assistance of the National Baby Week Council, has decided to follow up the policy successfully pursued in the case of Infant Boy Mortality. It therefore offers three awards of £25 and three second awards of £10 for districts which reduce their death-rates of children aged one to five this year (1924) to the greatest extent, as compared with the previous three years.

The awards are respectively for districts between 5000 and 20,000 population, 20,000 and 50,000, and towns over 50,000. The adjudication will be undertaken by the National Baby Week Council.

Full details will be sent to anyone enclosing stamped, addressed envelope to "Death Rate," the *Daily News*, Bouverie Street, London, E.C. 4.

University of London.

NOTICE IS HEREBY GIVEN that the Senate will proceed to elect EXTERNAL EXAMINERS for the calendar year 1925 or the Examinations above Matriculation as follows. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included. Where Examiners are to be appointed for (*a*) Intermediate Examinations only, and (*b*) Final and Higher Examinations only, the fact is indicated after the name of the subject below; in these cases the same Examiner cannot hold both appointments.

For the Calendar Year 1925.

For the First Examination for Medical Degrees.

BIOLOGY. PHYSICS.

For the Second Examination for Medical Degrees.

CHEMISTRY (two). PHYSIOLOGY.

Higher Examinations for Medical Degrees.

MEDICINE (two). OBSTETRIC MEDICINE.
MENTAL DISEASES. STATE MEDICINE.
NEUROLOGY. SURGERY.
TROPICAL MEDICINE.

N.B.—Attention is drawn to the provision of Statute 124, whereby the Senate is required, if practicable, to appoint at least one Examiner who is not a Teacher of the University.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, 7th July, 1924. (Envelopes should be marked " Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted, one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for, a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senato in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

E. C. PERRY, Principal Officer.
University of London, South Kensington, S.W. 7,

Under the Personal Direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES.

An Accountant's Certified Report is required in respect of every Practice or Partnership the disposal of which is undertaken by the Agency.

The commission chargeable in respect of any Practice in Great Britain placed exclusively in the hands of the Agency for transfer has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being £50. In the case of Foreign and Colonial practices similarly placed the maximum is £75.

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUMS TENENS OR ASSISTANTS.

Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. SOUTH-COAST. — Large Town. — PARTNERSHIP — A Quarter or One-third Share in a Middle- and Working-class Practice. Income over £4000, with scope. Panel of over 4000. Fees 2s. 6d. to 7s. 6d., chiefly 3s. 6d. to 5s. No Midwifery and very little night work. Purchaser should preferably be not over 35. Premium 2 years' purchase.
2. DERBYSHIRE. — Old-established unopposed Country PRACTICE within 6 miles of a large Town. Cash receipts for the past 3 years average £1300 per annum, including union and vaccination £100 and 700 panel patients. Visits 2s. 6d. to 7s. 6d. Midwifery 2 to 10 guineas, 20 cases yearly. Attractive Georgian Residence (recently decorated), containing surgery, waiting-room, dispensary, 2 reception-rooms, 4 large bedrooms, 3 attics, bathroom, very nice garden, garage ; gas laid on ; rent £50. Premium £2000, including drugs, fittings. Educational facilities for boys. Excellent hunting, fishing, shooting, boating.
3. WEST RIDING.—Hospital Town, within easy reach of a University City. Well-established PRACTICE, producing an average of about £2000 per annum. Panel of over 1000. Suitable house available. Premium 1½ years' purchase.
4. DERBYSHIRE. — Hospital Town. Old-established PRACTICE, held 13 years by present Incumbent, who is relinquishing on account of ill-health. Cash receipts for the past 3 years average £3372 per annum, including about £1500 from panel. Fees 3s. 6d. to £1 1s. About 50 cases of Midwifery a year at 2 to 5 guineas. Centrally situated house (2 reception-rooms, consulting- and waiting-rooms, 4 bedrooms, bathroom, &c.) on lease at £100 a year. Premium £5000. Good scope for surgery, and Vendor is on the Staff of the Hospital.
5. SOUTH MIDLANDS.—Residential Town. Old-established, mainly better-class non-dispensing PRACTICE. Income about £2000 a year. Small selected panel of 500–600. Fees 2s. 6d. to 21s., mainly 7s. 6d. to 21s. Midwifery 2 to 25 guineas ; 10 cases last year. House with 3 reception, 7 bedrooms, garden ; rent £100 a year. Premium 2 years' purchase.
6. NORTH-EAST COAST.—Favourite Resort. Small old-established non-dispensing PRACTICE. Income £400, with very large scope for young, energetic, well-qualified man. Fees 5s. and 7s. 6d. Prominent corner house, 3 reception-rooms, 6 bedrooms, garden. Vendor's own freehold. Premium for house and practice £2500.
7. SOMERSET.—Unopposed PRACTICE. Old-established Mixed-class Practice. Average income £1283, including appointments, and panel of over 1000. Very nice house with 2 reception-rooms, professional rooms, 7 bedrooms, garage, garden ; rent £43. Sport of all kinds. Premium £2250.
8. BRISTOL.—Very sound Middle- and Working-class PRACTICE, held nearly 25 years by present Incumbent, who is relinquishing on account of ill-health. Average cash receipts over £1200 a year, including several small appointments and a panel of over 1300. Visits 3s. 6d. to 10s. 6d. Midwifery from 3 guineas. Very good house, specially built for a doctor, contains 2 reception-rooms, waiting-room, consulting-room, and surgery with separate entrance, 5 bedrooms, &c., garden. Premium £1800
9. SEASIDE RESORT.—NORTH-WEST COAST.—Old-established good-class PRACTICE (held 25 years by present Incumbent), averaging £1310 per annum for the past three years. No panel and practically no Midwifery or night work. Visits 7s. 6d. to £1 1s. Car not kept. Good house (facing sea) ; rent £150. Premium 1½ years' purchase, or reasonable offer, and suitable terms would be arranged. Vendor selling on account of ill-health.
10. LINCOLNSHIRE.—Unopposed Country PRACTICE. Very easily worked ; average income over £1100. Fees 2s. 6d. to 10s. 6d. Very little Midwifery. Good detached house in its own grounds ; rent £80 on lease. Premium £1600, part by instalments.
11. JUNIOR PARTNERSHIP.—EAST-COAST TOWN. (Over 100,000 inhabitants.)—A gentleman who should be married, under 35 years of age and have held a Hospital appointment can acquire the Fifth Share (to commence with, which will produce over £1000 per annum), in a leading and old-established non-panel Practice. Visits 5s. upwards. Midwifery from 2 guineas. 130 cases yearly. Very good house available, containing 3 reception-rooms, 5 bedrooms, bathroom, &c., and garden : rent £60 on lease. Premium 1½ years' purchase. Prospects of Surgery.
12. NORTH-EAST MIDLANDS.—Country PRACTICE within easy access to large Town. Very old established, and held by the Vendor over 20 years. Average income about £800, including appointments and panel of 480. Nearest opposition 5 miles. Fees 3s. 6d. to 20s. Large freehold house with 3 acres of garden. Price £2500. Premium for practice £1500.
13. LONDON, WEST-END.—PARTNERSHIP. — A Quarter Share (to commence with) and up to one-third in 2 years, and one-half in 4 or 5 years, with ultimate succession if desired, is for disposal in a first-class General Practice. Income for the immediate past year £3020. Fees mostly 1 guinea upwards, and a few at 10s. 6d. Purchaser should be a Graduate or hold some higher qualification. Premium for the quarter share £1500.
14. GLOUCESTERSHIRE.—Very sound Country PRACTICE, held by Vendor nearly 20 years. Steady average income of £1450, including a panel list of 1177. Practice is situated in extremely beautiful country. Good freehold house, with garden. Rent £65. Premium £1800, £1000 cash, and balance by instalments.
15. SOUTH-WEST OF ENGLAND.—Country PRACTICE. Small, practically unopposed, in very pretty country. Income nearly £500, with considerable scope. Fees 2s. 6d. to 10s. 6d. Nice house with good accommodation on long lease ; rent £60. Excellent sport. Premium for practice and lease £800.
16. PARTNERSHIP.—SURREY.—Residential Town (population over 25,000) in a beautiful district, a Two-fifths Share —producing nearly £850 a year—in an old-established, practically non-dispensing, Practice, held by Vendor 20 years, is for disposal. Receipts average £2110 per annum, including appointments £93 and panel of about 1,700. Visits 4s. to 10s. 6d. Midwifery 3 guineas upwards ; 30 cases yearly. Premium [illegible] years' purchase. Ingoing partner should be well qualified, under 35 years of age, and if possible a Gynæcologist. Good society, golf, tennis, &c.
17. YORKSHIRE.—Large clean Town. Well-established Middle- and Working-class PRACTICE. Income £1300, including £580 from panel and £350 from appointments. Advice and medicine from 2s. 6d. ; visits and medicine 3s. 6d. upwards. Very little Midwifery ; lowest fee 2 guineas. Good detached freehold house, with small garden, electric light, garage. Price £2500, of which £1500 could remain on mortgage. Premium £1400 cash.
18. NORFOLK COAST TOWN.—Old-established PRACTICE, held by Vendor many years. The average income is only about £600, but there is large scope for increase. Small panel of about 300. Fees 3s. 6d. to 1 guinea. Very little Midwifery. Well-situated house with small garden : rent £180 on lease. Premium £900.
19. CHESHIRE.—Twelve months' PARTNERSHIP Introduction will be given to an old-established Middle-class and Panel Practice (1600 patients on list), worth last year £2100. Situated in a large Town (population nearly 100,000) close to Seaside Resort. Visits 2s. 6d. to 5s. Midwifery 2 to 3 guineas ; about 100 cases yearly. Car not required. Good house, with garage, available at end of introduction. Premium 1½ years' purchase.
20. NEW ZEALAND (NORTH ISLAND).—Unopposed and increasing PRACTICE in a very beautiful district on main line, about 36 miles from a large City, and worth nearly £1300 a year, including easily worked appointment at £100. Visits in township 10s. ; mileage 6s. Midwifery 5 guineas. Good and up-to-date house (built by Vendor's predecessor) containing surgery, [illegible] reception-rooms, [illegible] bedrooms, and sleeping porch, bathroom, &c., with an acre of ground, tennis-court, &c. ; rent £120 on lease. Climate perfect, sport of all kinds, telephone, churches, and shops of every description. Premium £1000.
21. LONDON, EAST.—Well-established Middle- and Working-class PRACTICE. Income over £1150. Panel of 1300. Surgery fees 2s. 6d.; visits 3s. 6d. upwards. No Midwifery. Well-situated house ; will be sold or let. Premium £1750.

Profits accruing to Bovril, Ltd., from the Agency will be allocated among recognised Medical Charities.

Full Schedule of Terms and Conditions will be forwarded on application.

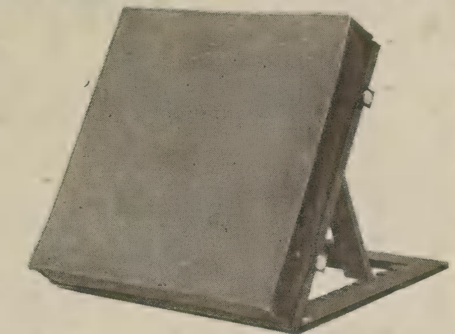
MOSELEY FLOAT-ON-AIR

(Patent)

AIR-BEDS, BACK-RESTS

and other Invalid Specialities.



BEDREST, with Detachable Cushion, covered in dark blue waterproof cloth. Folds flat. Size 18 in. × 18 in.

Constructed on the celebrated tubular system (fully protected by patent) which is being used with conspicuous success for Motor Upholstery. The Moseley Float-on-Air system depends upon a very low air-pressure producing cushions of extreme softness, which are particularly suitable for invalids. The tubular construction prevents the air from being driven away from the point of contact—washable, easily disinfected, and most convenient.

Quotations and full particulars on receipt of requirements.
